Forming a coral atoll in the North Pacific Ocean, about one-third of the way from Honolulu to Tokyo, the Midway Islands were formally claimed by the United States in 1867. The first inhabitants arrived in 1903 in concomitance with the lying of the trans-Pacific cable, which passed through the islands. In 1996, Midway opened to the public as a wildlife refuge, but having closed in 2001 for reorganization, it remains off-limits to this day. The population now consists of about 40 people, the staff of the U.S. Fish and Wildlife Service, a division of the Department of the Interior. The official language of Midway is English.

Introduction: Migration, Language Diversification, and Contact

Migration – that is, the permanent or temporary movement of people from one geographical area to another – has been a constant of human history since earliest times and has shaped the areal distribution of languages and the history of linguistic groups.

Language diversification and spread as a consequence of migration underpins the histories of large language families, such as Indo-European, Sino-Tibetan, Austronesian, and Afro-Asiatic. The geographical dispersion of languages belonging to these families is the result of large-scale prehistoric migrations, reflecting both military invasions and agricultural expansion. Language diversification through people movement and the subsequent communicative isolation of the migrating group is depicted in the classic *Stammbaum* or family tree model of language change: each split in

the diagram reflects a situation where people occupying a geographical area divided, and one group settled in a new, nonadjacent territory.

Migration movements not only support language diversification through geographical dispersion, but also create the conditions for inter-group contact and linguistic convergence, that is, structural borrowing and the leveling of marked distinctions between dialects and languages (*Sprachbund* phenomena and koinéization/dialect leveling). Contact between different linguistic groups also leads to the formation of new forms of speech: trade jargons and other contact languages (pidgin/creoles, mixed languages, second language varieties) have emerged as a direct result of human mobility.

Migration movements are particularly prevalent in times of accelerated social, political, and economic change (e.g., demographic growth, technological innovation, political conflict and persecution, economic deprivation and poverty). Wars, industrialization, colonialism, and the subsequent emergence of a global capitalist world market have all led to high rates of national and transnational migration, and have shaped states and societies across the world (Castle and Miller, 1998).

Dialect Leveling and Dialect Formation

Whereas traditional dialectologists often evoked an idealized 'linguistics of isolation and immobility' (Chambers, 2002: 117) – epitomized in the construct of the 'non-mobile, older, rural male' (NORM; cf. Chambers and Trudgill, 1998) as the ideal informant – modern dialectologists and sociolinguists have shifted their attention to the systematic study of the linguistic consequences of geographical mobility. High levels of rural-to-urban migration have not only contributed to the gradual decline of traditional rural dialects (dialect loss), but new composite dialects have crystallized rapidly in urban environments. London, for example, has always been characterized by high levels of in-migration and linguistic mixing. In the 16th century the emerging London norm was significantly shaped by the influx of large numbers of northerners into the city. Some northern dialect forms, such as, e.g., the northern third person plural marker *–(e)s* (*know(e)s* vs. southern *–th*, *knoweth*), were incorporated into the emerging norm of London English (and subsequently into standard English; Nevalainen, 2000).

The development of planned urban communities in areas targeted for industrial expansion in the 1960s and 1970s, the so-called new towns, offered linguists an opportunity to study processes of dialect mixing and leveling in real time. Kerswill and Williams (1992; also Kerswill, 1996) compared the speech of children in Milton Keynes, a new (1969) urban development near London, with that of their parents who had moved to the town from elsewhere in the southeast, and also northern England and overseas. They found that the children's dialect lacked regional distinctiveness, and differed both from their parents' dialects and from the local dialects spoken in the nearby areas. Children used various linguistic strategies in their creation of the new dialect: they avoided strong regional forms used by their parents, developed phonetically intermediate forms, which mediated between the various dialect inputs, and generally preferred forms that were similar to the non-localized, RP-like southeastern norm.

Dialect leveling also played a major role in colonial settlements. In South Africa, Australia, and New Zealand relatively homogenous colonial dialects developed on the basis of the diverse input dialects of the migrating settlers (Trudgill, 1986; Chambers, 2003: 65ff.).

In multilingual countries (e.g., South Africa, Switzerland) urbanization also led to the formation of multilingual cities (in other countries this development is a consequence of transnational migration): Xhosa, the language of many rural-to-urban migrants in South Africa, is now a major language in Cape Town (next to Afrikaans and English), and French and Italian are competing with Swiss-German in Basel, a historically German-speaking town (Lüdi, 1995).

Whereas traditional dialectological and sociolinguistic studies stipulated that their subjects should be locals (or have arrived in the area before the age of seven, i.e., at an age when they could still master the phonological complexities of the dialect), Chambers (2002) argued for the need to include non-local residents into modern dialect surveys. He introduced migration as an independent variable using the Regionality Index (RI), which identifies the migration history of informants on the basis of the following indicators: place of birth of informant, place of birth of parents, area where respondent grew up, and area of residence. The RI is similar to the 'combined birth-country criterion,' i.e., birth country of person as well as parents, which is used in transnational migration research (cf. Extra and Gorter, 2001).

Bilingualism, Language Shift, and Maintenance

In some cases migrating people have imposed their language(s) on the indigenous population: the southward migration of Bantu-speaking groups (starting around 1000 B.C.) led to the absorption or displacement of indigenous hunter-gatherer communities; the Roman Empire spread its language through warfare

and conquest; European colonial settlements transformed the political and linguistic landscapes in Africa, the Americas, and Asia. In-migration of powerful groups can thus contribute to the creation of indigenous minority groups and/or language shift. Less powerful migrant groups usually assimilate to the dominant language of the new society: the French Huguenots who arrived in South Africa in the 1680s adopted Dutch, the dominant language of the colony; in the 20th century Jewish migrants to the United States adopted English, in earlier migrations their ancestors had adopted Lithuanian and Polish (which they used alongside their ethnic language, Yiddish). Bilingualism and code-switching are frequently observed among second and third generation migrants, where they become markers of the migrants' hybrid, bi-cultural identities (cf., for example, Zentella's 1997 study of Spanish-English code-switching in El Barrio, a Puerto Rican neighborhood in NYC; cf. also Dabène and Moore, 1995; a classic article on migration and hybridity is Park, 1928).

Long-term language maintenance is rare among migrants who move as individuals or in small family groups, and intergenerational language shift – which is indicated by the co-existence of different mother tongues within a household – is usually completed within three generations (Nahirny and Fishman, 1965). Clyne (1991) has shown on the basis of his analysis of the Australian census information that the rate of shift differs across migrant language groups. Important variables, which support or delay language shift, are: settlement patterns (presence or absence of cohesive ethnic suburbs), endogamy, cultural distance from the host society, contact with the home country, and cultural values attached to language. Horvath (1985), in her study of vowel variation in Australian English, has illustrated how Italian and Greek migrants are gradually incorporated into the Australian English speech community: first-generation migrants form a peripheral group (she describes their English as 'accented' and 'ethnic broad'; basically, they use second-language varieties), second-generation migrants were full (usually bilingual) members of the host speech community.

Group migration tends to delay language shift. Long-term intergenerational language maintenance has been documented for the so-called *Sprachinseln* ('language islands' or language enclaves). These geographically-bound territories are typically located in rural areas and reflect the cohesive settlement patterns of the original migrants. Subsequent generations maintain their linguistic and cultural/religious distinctiveness from the surrounding host society. Well-known examples of linguistic enclaves are the German-speaking settlements in eastern and southeastern Europe that were formed as a consequence of migrations since the Middle Ages, and also the 18th century Amish settlements in North America. Language maintenance in these areas occurs in functional complementarity with the language(s) of the host society (cf. the papers in Berend and Mattheier, 1994). Community bilingualism, however, affects the structures of the heritage language, and heavy lexical and structural borrowing are commonly observed (cf. Louden on Pennsylvania Dutch in Berend and Mattheier, 1994).

Mass Migration and Language Formation

The forced mass migrations associated with slavery have led to the formation of stable contact languages in Africa, the Caribbean, and Asia. The plantation system created a catastrophic break in linguistic tradition: captured slaves not only spoke a variety of diverse native languages, but they also dramatically lost all contact with their homeland, did not share a lingua franca with the other slaves, and had only minimal access to the dominant colonial language of their masters (Sankoff, 1979). The pidgin/creole languages that emerged in these contexts supplanted the original languages of the slaves, and became the basis for the formation of new cultural and linguistic communities in the diaspora.

The situation was different in the case of indentured labor migrations that took place in the mid- to late 19th and early 20th centuries. Although work conditions were generally poor and laborers were often coerced into employment, it was, at least in principle, possible to return home upon completion of the contract. Moreover, unlike slaves, indentured workers did not form "a pulverized mass of individuals from several tribes, but instead they were limited to men of a few nationalities, who found themselves together in a situation in which community life of a sort was possible" (Reinecke, 1969: 114). Conditions were thus generally favorable for language retention, and inter-dialect leveling has been described for the transplanted languages of indentured workers (Mesthrie, 1991 with regard to Bhojpuri in South Africa). At the same time workers acquired a knowledge of the language(s) of the host society. These second language acquisition processes contributed to the creation of new varieties of the dominant language, which replaced the workers' original mother tongues after several generations in the diaspora (cf. Mesthrie, 1992).

Structural similarities between pidgin/creole languages and the outcomes of second language acquisition in the context of mass labor migration have been explored systematically with regard to

fossilized interlanguages such as, e.g., *Gastarbeiterdeutsch* ('guest workers' German'; cf. Clyne, 1968 for an early discussion), and also 'immigrant Swedish' (e.g., *Rinkeby* Swedish, as described by Kotsinas, 2001). Both varieties show grammatical reduction and phonological simplification akin to pidgin languages (cf. also Smart, 1990 for a description of pidgin Arabic used by Asian labor migrants in the Gulf states). However, a stable contact language did not emerge among second generation migrants in either Germany or Sweden. Instead, teenagers with a migrant background have been found to use a stylized pan-ethnic form of the local language that incorporates certain features (e.g., phonology, intonation) of their parents' second language. This pan-ethnic variety of the target language is seen as 'deficient' by native speakers, but serves as a symbolic badge of membership in the larger migrant community (on the ideological implications of popular debates about *Rinkeby* Swedish, see Stroud, 2004). A similar phenomenon has been described for Australia where such speech forms are colloquially referred to as *wog-speak* ('wog' can be used in a self-mocking sense by migrants to designate their bicultural identity; Warren, 1999; Clyne *et al.*, 2001). Under conditions of social segregation and intergroup conflict, such ethnolectal developments can lead to long-term processes of linguistic divergence and the development of oppositional linguistic (sub-)cultures.

Transnational Migration, Language, and Citizenship

Transnational migration has grown in volume and significance since 1945. High levels of in-migration have changed the demographic, economic, and social structures in many countries and have led to the formation of new ethno-linguistic minorities (cf. the papers in Extra and Gorter, 2001 and Extra and Verhoeven, 1998). Transnational migration is largely an urban phenomenon. Fraser Gupta (2000) uses the term 'cosmopolis' to describe multilingual urban settings that have been created by waves of migration, and where the individual's linguistic and cultural repertoires are characterized by a multiplicity of registers, languages, and cultural traditions (cf. also Castle and Miller, 1998 on the rise of 'global cities').

Many countries have recognized the necessity of introducing special language services for new arrivals, and education has been a key site for the implementation of migrants' linguistic rights. Policies that accept the cultural differences created by migration and grant minority linguistic and cultural rights to migrants have since the late 1970s been instituted in countries such as Australia, Canada, and Sweden. In Australia the Adult Migrant English Program (AMEP) offers up to 510 hours of ESL lessons to adult migrants, and special school-based programs exist for children. At the same time Australia's language policy aims to develop and maintain languages other than English within the school curriculum and also radio, TV, and print media. In Australia (also Canada and the United States) heritage language education, which focuses on developing appropriate teaching methods for second and third generation migrants, has developed into an important branch of second language pedagogy.

However, multilingual programs have come under attack in Australia (and elsewhere) since the mid-1990s: linguistic and cultural diversity are increasingly viewed as a threat to national homogeneity, and there has been a marked policy shift in favor of emphasizing the teaching of English. As a result bilingual programs and services have been reduced (a similar development has been observed in Sweden: see the articles by Boyd, Ozolins, and Clyne in Extra and Gorter, 2001; for the United States cf. Crawford, 2000). Assimilatory language policies see linguistic and cultural integration as a prerequisite for citizenship, and exclude the migrants' bicultural and bilingual identities from the public sphere.

Conclusion: Migrants as 'New' Ethnic Minorities

Today, migration is a central force in social transformation, international relations, and domestic policy in countries as diverse as Germany, Malawi, and Singapore. Chain migration (secondary migration of family members) and migrant's social networks, which encourage and facilitate settlement in a new country, can lead to the formation of ethnic enclaves in societies with large migrant populations. The subsequent development of community networks and institutions (social clubs, churches, etc.) in the host society gradually transforms transitory migrant groups into permanent and relatively cohesive 'new' ethnic communities. Like 'historic' indigenous minorities, migrant minorities are usually vulnerable populations whose linguistic and cultural rights need to be addressed and protected by national language policies and planning.

Ideologies Toward Immigration

In addition to the traditional forms of migration, there are new forms of population movements, such as overseas students and highly qualified professionals, who mostly offer their knowledge and expertise on universities to transnational companies. This new form of population movement is an essential component of the globalization process, and it results in increasing language diversity in the host societies. It is important to remember that immigrant minority (IM) groups do not create their communities in

Migration and Language Planning

G Extra and K Yağmur, Tilburg University, Tilburg, The Netherlands

Ideologies Toward Immigration

In addition to the traditional forms of migration, there are new forms of population movements, such as overseas students and highly qualified professionals, who mostly offer their knowledge and expertise on universities to transnational companies. This new form of population movement is an essential component of the globalization process, and it results in increasing language diversity in the host societies. It is important to remember that immigrant minority (IM) groups do not create their communities in

isolation; they interact with the mainstream society, mostly, in the social and legal frameworks provided by the receiving society. The connection between source and destination countries is an inherent aspect of the migration phenomenon. The type of connection varies depending on the type of migration, whether it be the push or pull factor. In addition, receiving societies' integration policies have a decisive role concerning the integration patterns and language use of IM groups.

As documented by Extra and Yağmur (2004), the legal status of IM groups within host societies is not as straightforward as that of regional minorities. In most immigration contexts, legally, socially, and economically, immigrants are not considered to be equal members of the mainstream society; instead they are often considered as temporary, marginal, or even undesired within the host society. In this way, state policies may define the social-psychological reality of being an immigrant and accordingly, may influence the sociocultural orientation of immigrants. In the literature, four clusters of state ideologies shaping integration and language policies of immigrant-receiving societies are identified (Bauböck *et al.*, 1996; Bourhis, 2001; May, 2001; Penninx, 1996). These ideologies range from pluralism to ethnist ideologies, in terms of pluralist, civic, assimilation, and ethnist ideology.

Pluralist ideology proposes duties and responsibilities to be observed by all members of the society. In this ideology, learning the official or mainstream language is the responsibility of the citizens themselves, and the state provides opportunities to facilitate language learning. Concerning the home languages of citizens, the state has no mandate in defining or regulating the private values of its citizens in the domestic domain, nor their political or social affiliation. As different from other ideologies, the state provides financial support for mainstream language classes and for cultural activities to promote first language maintenance. Australian and Canadian multicultural policies are good examples of the pluralist ideology as presented here.

Civic ideology expects that immigrants adopt the public values of the mainstream society. Like pluralist ideology, the state does not interfere with the private values of its citizens but unlike pluralism, the state does not make any provisions for the maintenance or promotion of linguistic or cultural values of IM groups. A typical example of civic ideology might be the Netherlands. Given the centuries-old coexistence of people varying in descent, religious denomination, culture, and class, the Netherlands might be considered to be a plural society. In discussing the relationship between integration of immigrants and pluralism, Vermeulen and Penninx (2000: 3) assume that the tradition of religious pillarization in the Dutch society can be associated with pluralism. Yet, Penninx (1996) argues that due to nation-state ideology, Dutch state policies cannot be identified as pluralistic. Nonetheless, the long-standing pillarized structure of the Dutch society has acted as a barrier against assimilationist or ethnist ideologies.

Assimilation ideology expects IM groups to comply fully with the norms and values of the mainstream society. As different from pluralist and civic ideologies, assimilation ideology expects complete linguistic and cultural assimilation into the mainstream society. In the name of homogenization of the society, assimilationist language policies aim at accelerating the language shift and language loss of IM groups. With its unitarian approach, French policies fit the assimilationist ideology cluster quite well. Recent political developments, such as restrictions on marriage partners of IM groups, abolition of community language classes, and compulsory integration classes in Denmark show a strong shift toward assimilation ideology. During the last few years, the Netherlands has moved in the same direction (Extra and Yağmur, 2004) Such shifts prove that changing political circumstances have a profound effect on integration and language policies of immigrant-receiving countries. Basically, all nation-states are assimilationist in nature. According to Waldinger and Fitzgerald (2004: 1179), "as ideology of the nation-state society, the sociology of assimilation necessarily obscures coercive efforts to build a nation-state society by excluding outsiders – via control of external borders – and to distinguish between members and unacceptable residents of the territory – through regulation of the internal boundaries leading to citizenship and legal residence." For most immigrants the link between old-ancestral homeland and the new country of residence is an inevitable reality, and contributes to the shaping of a transnational identity; but for the nation-state ideology, that link and identity are difficult to accept. Irrespective of the traditional and conservative discourse on immigration and integration, however, IM groups maintain, build and reinforce multiple connections between their old and new homelands. In the contemporary era of migration, such linkages maintain and reinforce the dynamism of globalization. Yet, especially in nation-states, IM groups are often conceived as aliens, and they are subject to different treatment. Different language policies with respect to regional vs. IM groups highlight the unfavorable position of the latter in assimilationist societies.

Ethnist ideology shares most aspects of the assimilation ideology; yet it makes it difficult for IM groups

to be accepted legally or socially as full members of the mainstream society. Citizenship and naturalization laws are quite representative for distinguishing ethnist ideologies. The principle of *ius sanguinis* ('law of the blood') underlies acquisition of citizenship in such countries. For instance, while third-generation Turkish immigrant children born in Germany are not automatically entitled to German citizenship, German repatriates, most of whom cannot even speak German, coming from ex-Soviet Union countries, are granted German citizenship. On the policy level, ethnist ideology seems to favor full linguistic and cultural assimilation of IM groups, but in reality achieving full membership is not easy. Even though there is variation between the policies of various states in Germany, federal state ideology in Germany can be identified as ethnist in nature.

Even though different IM groups exhibit different reactions to the above policies, generally speaking, host societies' policies have an effect upon their integration and language use patterns. Depending on the extent to which IM groups consider their own language as part of their core values, they either maintain their first language or shift to the mainstream language (Smolicz, 1981).

Sociolinguistic Outcomes of Migration

Emigration processes inevitably lead to a rupture with the original L1 community, and to contacts with a new and dominant L2 community. As a consequence of reduced L1 input, processes of L1 erosion may occur, leading to, for example, reduction of stylistic variation or overextension of morphosyntactic rules. IM groups often use their L1 in the domestic domain but they mostly use the mainstream language outside the home context. Varying degrees of L1 and L2 use bring up the issues of language maintenance, shift, and loss. Language maintenance usually refers to relative language stability in the number and distribution of its speakers, its proficient usage by children and adults, and its retention in a number of domains (Baker, 2001: 59). The choice and the efforts of maintaining an IM language may be made on the basis of the instrumental functions of the language involved or on the basis of its symbolic functions such as group identification and cultural identification (Kipp *et al.*, 1995). An individual's maintenance of the L1 in an L2 environment is usually referred to as language retention (Hyltenstam and Stroud, 1996). The opposite of societal language maintenance is termed language shift, and the term 'language loss' is used for the opposite of language retention (*see* **Language Maintenance and Shift**). How much societal use of a first language is considered language maintenance or how much societal use of a second language is considered language shift cannot precisely be specified. Generally, language shift is used in the literature to refer to a negative language development. "There is a reduction in the number of speakers of a language, a decreasing saturation of language speakers in the population, a loss in language proficiency, or a decreasing use of that language in different domains. The last stages of language shift are called language death" (Baker, 2001: 59).

It can be argued that language attrition is an intragenerational phenomenon while language shift is intergenerational. The term 'intragenerational' implies that the loss of linguistic skills takes place within individuals over a more or less extended period of time, mainly because of a break in linguistic continuity. With respect to intergenerational and intragenerational language loss, an examination of Gonzo and Saltarelli's (1983) well-established model is helpful for the differentiation between language attrition and language shift. In relation to the sociolinguistic situation in IM families, Gonzo and Saltarelli suggested that, because of nonuse of L1 and influence from L2, first-generation immigrants experience language attrition over the years. The children of these immigrants acquire the already attenuated L1; even this reduced system is, however, not entirely passed on to the second generation for a number of (socio)-linguistic reasons. Following this incomplete L1 acquisition, there is again L1 attrition among second-generation immigrants, and even further reduced forms are transmitted to the third generation. This cascade model thus predicts that within three or four generations, IM languages in contact with a mainstream language are doomed to be lost (Gonzo and Saltarelli 1983). This view is supported by Fishman's (1991) conclusion that a number of language contexts that unless the minority language is an indigenous one, the shift to the mainstream language is almost irreversible. Yet it is important to point out that language loss is not an isolated phenomenon; rather it is a special case of variation in the acquisition and use of language(s) and can best be studied within a larger framework that includes other phenomena of L1/L2 acquisition, bilingualism, language use and choice, code-switching and mixing, and language attitudes (Yağmur, 1997).

In order to systematically investigate minority language contexts, various language use typologies have been proposed, including the well-known and frequently cited works of Ferguson (1966), Haugen (1972), Haarmann (1986), and Bourhis (2001). Each of these frameworks considers a particular set of linguistic and social factors to be essential for an accurate description of language contact situations.

In addition to these models, a number of sociolinguistic and social-psychological models have been proposed to investigate language maintenance and shift (Kloss, 1966; Giles *et al.*, 1977; Smolicz, 1981; Conklin and Lourie, 1983; Fishman, 1991; Edwards, 1992). These models have been tested in different contexts with different language groups. Clyne (1991, 2003) and Kipp *et al.* (1995) have tested the relevance of some of these models against Australian Census data (for a comprehensive account, see Clyne, 2003).

The factors involved in language maintenance or shift are divided into two categories: those affecting a speech community and those affecting individuals within a speech community (Kipp *et al.*, 1995). In that division, birthplace, age, period of residence, gender, education and qualifications, marriage patterns, prior knowledge of the mainstream language, reason for migration, and language variety are included in the category of individual factors. Group factors are listed as "size and distribution of an ethnic group, the policy of the host community towards community languages, the position of the language within the cultural value system of the group, and proximity or distance of the community language to or from English" (Kipp *et al.*, 1995: 123). However, Kipp *et al.* admit that it is not always easy to draw the line between individual and societal factors, as there is an ongoing interaction between an individual and the speech community that he or she belongs to. In most cases, these factors are interrelated, both on the individual and on the group level.

Researchers in immigrant-receiving societies have carried out detailed studies on various aspects of language use among migrants. These studies range from early bilingual development to language loss. Bilingual development among school children and various models of bilingual programs are another field of study. Code-switching and borrowing, as well as language maintenance and loss are issues resulting from language contact and migration. For a detailed discussion of such research issues and findings, readers are referred to research monographs and edited books such as Ammerlaan *et al.*, 2001; Extra and Verhoeven, 1993, 1998; Fase *et al.*, 1992; Klatter-Folmer and Van Avermaat, 2001; Lambert and Freed, 1982; Schmid *et al.*, 2004; Seliger and Vago, 1991; Weltens *et al.*, 1986; Yağmur, 1997.

Miklosich, Franc (1813–1891)

N Kerecuk, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Franc K. Miklosich was a Slovenian philologist specializing in Slavic philology. Born in Ljutomer, Styria, Slovenia, then part of Austria, he graduated as a doctor of philosophy from the University of Graz where he subsequently taught philosophy. In 1938, he went to Vienna to read law but dedicated his life to Slavic philology. From 1844 to 1862, he worked at the Imperial Library. In 1849, he was appointed as a professor of the new chair of Slavic philology at the University of Vienna and worked there until 1866. He became a member of the Academy of Vienna, which appointed him as the secretary of the historical and philosophical section. He is credited with introducing the historical and comparative method to the Slavic languages. He is held in great esteem by Ukrainians because he recognized Ukrainian as a separate language. He also wrote on Romanian, Albanian, Greek, and the languages of the Roma and Sinti people. Miklosich edited various texts in ethnography and history, and he was described as a man of great erudition. He was interested in public education and was a member of the council of public instruction and was a corresponding member of the French Academy of inscription.

Miklosich followed from Grimm's work in comparative and historical linguistics and published on the Slavic languages from 1852 to 1874. His first early major contribution was a review of Bopp's *Comparative grammar*. He followed Grimm's and Diez's models of syntax. Syntax for Miklosich was the study of word classes or forms and their meaning. This was characteristic of other Indo-Europeanists, who tended to concentrate on morphosyntax and pursued extensive description of the categories of the languages they researched. The fourth volume, his *Vergleichende Grammatik der slavischen Sprachen*, is on syntax (1852–1875, 2nd edition 1876–1883). He also wrote on impersonal forms such as 'it is snowing.' He was awarded the Volney Prize for the 1856 third volume of the *Vergleichende Grammatik*. Following Pott's list of roots, Miklosich (1886) prepared an etymological dictionary for the Slavic languages, as did Benfey (Greek), Curtius (Greek), and Diez (Romance). His contributions to lexicography are significant. B. Delbrück (1880) refers to Miklosich's role along with Schleicher's in pursuing work on the Slavonic languages, comparing them to what Bopp and Grimm did for the Germanic

Mill, John Stuart (1806–1873)

S-H Seong, University of Bonn, Bonn, Germany

© 2006 Elsevier Ltd. All rights reserved.

John Stuart Mill (1806–1873) is regarded as the most influential British philosopher of the 19th century. He counts as one of the representative 19th-century philosophers who developed grand theories encompassing philosophy, ethics, language sciences, politics, and social sciences. He is also well known as one of the figures who effectively represent English empiricism and a liberal philosophical and political view of society and culture.

He was born on May, 20, 1806, in his father's house in Pentonville, London. His father, James Mill, had a great influence on the eldest son, J. S. Mill, from early childhood by providing him with a rigorous humanities training of the Greek and Latin classics. At about the age of 12, the intellectual interest of Mill was broadened to include philosophy, logic, politics, and economics. A utilitarian such as Jeremy Bentham, whose philosophical thinking James Mill pursued, counts also as one of the significant figures who influenced Mill early on in the development of his philosophical thought.

From May 1820, when he was 14 years old, Mill spent 1 year in France, continuing his laborious reading of various disciplines including chemistry, botany, and advanced mathematics. This visit made him fluent in the French language and he soon

languages in his *Introduction to the study of language* (Chap. III). His work became known in the Old Russian Empire. In 1863, O. O. Potebnia (A. A. Potebnja, 1831–1891), on his return from Berlin, attended lectures by Miklosich in Vienna. Potebnia's works contain a significant critique of Miklosich's works and on his syntax in particular.

Mill, John Stuart (1806–1873)

S-H Seong, University of Bonn, Bonn, Germany

John Stuart Mill (1806–1873) is regarded as the most influential British philosopher of the 19th century. He counts as one of the representative 19th-century philosophers who developed grand theories encompassing philosophy, ethics, language sciences, politics, and social sciences. He is also well known as one of the figures who effectively represent English empiricism and a liberal philosophical and political view of society and culture.

He was born on May, 20, 1806, in his father's house in Pentonville, London. His father, James Mill, had a great influence on the eldest son, J. S. Mill, from early childhood by providing him with a rigorous humanities training of the Greek and Latin classics. At about the age of 12, the intellectual interest of Mill was broadened to include philosophy, logic, politics, and economics. A utilitarian such as Jeremy Bentham, whose philosophical thinking James Mill pursued, counts also as one of the significant figures who influenced Mill early on in the development of his philosophical thought.

From May 1820, when he was 14 years old, Mill spent 1 year in France, continuing his laborious reading of various disciplines including chemistry, botany, and advanced mathematics. This visit made him fluent in the French language and he soon

became acquainted with French history and philosophical thought. In 1823, when he was 17, he began working as a clerk in the Examiner's office of the East Indian Company in which his father, James Mill, eventually became the Chief Examiner. In 1856, after having been in charge of the Company's relations with the native states for 20 years, Mill also becomes the Chief Examiner of the East Indian Company, succeeding Thomas Love Peacock. After retirement from this post in 1858, Mill was elected to the House of Commons in 1865. During his political career in the Parliament, he advocated for married women's property rights, women's suffrage, and women's equal access to education. It is sometimes maintained that it was through his relationship with Harriet Taylor, later his wife, that he came to be convinced that the promotion of the rights of women was crucial to the understanding of liberal culture as a form of modernity at that time.

As an important public figure during the Victorian era, his writing in philosophy and economics drew great general public recognition, more than any other thinker during the second half of the 19th century in England. His prolific academic activities centered around *The Westminster Review*, *The London Review*, and *The London and Westminster Review*. He died in Avignon on May 7, 1873 and was buried in the place beside the remains of his beloved wife, Harriet Taylor.

Mill is known as the key figure representing the so-called Utilitarianism in the philosophical tradition. Utilitarianism is a philosophical thought that the morality of any action or law is defined by its utility. Utilitarianism was proposed for the first time in England by Jeremy Bentham who formulated 'the greatest happiness principle.'

Mill was also influenced by the movements of Romanticism and Conservatism. After the deaths of Bentham and his father, James Mill, a suddenly created vacuum was filled by these intellectual movements and by the relationship with his wife, Harriet Taylor. Conservative Romanticists such as Thomas Carlyle and Samuel Taylor Coleridge had a great influence on Mill in the sense that they helped Mill turn away from radicalism. Mill's reading of later French thinkers such as Saint Simon and Auguste Comte and their French works on human science also played a crucial role in Mill's intellectual evolution. Mill and Comte both saw the drawbacks of the doctrinaire versions of the Enlightenment Project and the importance of the philosophy of history. As a disciple of Saint Simon, Comte held the view that history was a progressive process and that a scientific explanation is expressed in terms of empirically identifiable underlying causes, as opposed to speculative entities. This positivistic thinking required an explicitly identifiable and empirically confirmable explanation.

Mill was not intrinsically interested in the technical dimensions of philosophical thought. The technical considerations of philosophy were the basis for practical sciences and implications, for example, social sciences. Mill's discussion of the origins of knowledge in the *System of logic* became the foundation for his moral, political, and economic views. One of the targets that Mill wanted to debilitate in the philosophical and intellectual tradition in Europe was the philosophical position known as intuitionism, which was employed as the epistemology of political conservatism.

Intuitionism takes the view that innate truths exist independent of experience. Mill was opposed to the philosophical views of Kant, who claimed that there was *a priori* human knowledge. This philosophical view of Mill's is explicit in that Mill himself states in his *Autobiography* (pp. 233–235) contained in *Collectd works* (v. 1.) that "the System of Logic supplies what was much wanted, a text-book of the opposite doctrine – that which derives all knowledge from experience and all moral and intellectual qualities principally from the direction given to the associations... The notion that truths external to the human mind may be known by intuition or consciousness, independently of observation and experience, is, I am persuaded, in these times, the great intellectual support of false doctrines and bad institutions."

The traditional rationalist deductive mode of thinking is refuted in Mill. Mill develops the idea that all thinking processes are possible due to experience and that this proceeds through the association of ideas based on those experiences.

Even the most well-known traditional deductive way of argument such as the following is argued to be the result of an inductive way of thinking that started with individual experiences:

All men are mortal.
Socrates is a man.
Therefore, Socrates is mortal.

Based on our experiences and historical facts, we realize that all men die eventually. Therefore, this syllogism itself is thought to be the result of an inductive process. This way of logical thinking reflects Mill's political and social agenda in which he held the view that all customary human practice should be subject to revision or modification in the light of the constantly changing social and political circumstances and environments.

Mill's hostilities toward principles of innateness and intuitionism shaped his views on political

economics. Mill and other social reformers of that time voiced several major objections to intuitionism concerning its belief in the innateness of human nature, the inability to promote progressive thinking, e.g., utilitarianism, and the lack of a rational foundation and objectivity.

Through this empiricist thinking, it is obvious that Mill sees that the real world we live in is reflected purely in the ontology of language and logic that we use. In the light of modern linguistics, the parts of Mill's writings on logic (*System of logic*, 1843) are closely related to the study of meaning, i.e., semantics. The essence of Mill's theory of meaning is to be found in the first book of *A system: of names and propositions*; in Book 2, Mill discusses deductive reasoning, while Book 3 is reserved for induction.

Mill's contribution to linguistics can be positively evaluated with respect to the theory of reference and the theory of meaning. This discipline investigates the relations between linguistic expressions and their corresponding objects, facts, or events. Mill also uses for the first time the concepts 'denote' and 'connote,' i.e., the distinctive and oppositional technical terms, which are of prime importance to his semantics. For Mill, denotation has the function of direct reference. To this category belong proper names (Peter) and abstract names (truth), whereas "a connotative name is one which denotes a subject, and implies an attribute"(Mill, *Collected works* VII: 31). Mill further explains that "the word 'white' denotes all white things [...] and implies, or in the language of schoolmen, connotes, the attribute 'whiteness'" (Mill, *Collected works* VII: 31). This distinction between denotation and connotation is crucial for Mill's theory of meaning. It should also be noted that Mill did not distinguish the two categories in a fully consistent way.

According to de Jong (1992), Mill visualized language primarily from the standpoint of logic. Mill's work with respect to deductive logic is also often argued to fall near the transitional passage between Aristotelian syllogistic logic to modern logic. It is also the case that, from a modern perspective, his mode of thinking is treated merely "as a psychologistic variant of English empiricism" in the sense that Mill represents "a highly simple form of inductivism, while also his liberalism and his utilitarian views are often taken to be outdated" (de Jong, 1992: 402).

Mill's great intellectual achievements were *System of logic: ratiocinative and inductive* (1843), *Essays on some unsettled questions of political economy* (1844), and *Principles of political economy* (1848). In 1859, *On liberty* appeared, and his *Thoughts on parliamentary reform*. His *Considerations on representative government* was published in 1860; and in 1863 came his *Utilitarianism*.

In 1865, *Examination of Sir William Hamilton's philosophy* was published; in 1867, his Rectorial *Inaugural address* at St. Andrews University, on the value of culture; in 1868, the pamphlet on *England and Ireland*; and in 1869, his treatise on *The subjection of women*. Also in 1869, his edition of his father's *Analysis of the phenomena of the human mind* was published. After his death in 1873 were published his *Autobiography* (1873) and *Three essays on religion: nature, the utility of religion, and theism* (1874), written between 1830 and 1870.

George Armitage Miller, one of the fathers of and a chief driving force of modern cognitive science, was born on February 3, 1920, in Charleston, West Virginia. He studied at the University of Alabama (B.A. 1940; M.A. 1941), then at Harvard University, where he received an A.M. (1944) and a Ph.D. (1946) in psychology. He has been a professor at Harvard, MIT, Rockefeller University, and Princeton, where he is currently James S. McDonnell Distinguished University Professor of Psychology, Emeritus. Miller was President of the American Psychological Association (1969). Among the numerous honors conferred

upon him are Member of the American Academy of Arts and Sciences (1957), Member of the National Academy of Sciences (1962), Foreign Member of the Royal Netherlands Academy of Arts and Sciences (1985), American Psychological Foundation's Life Achievement Award (1990), and National Medal of Science (1991).

Miller's decisive contribution, as a key figure in the dramatic shift away from behaviorism to cognitivism, can be traced back to the late 1940s and the early 1950s, when he applied C. E. Shannon's information theory to his experiments, most notably those involving short-term memory capacity. Since then, the field of psychology has evolved into the collaborated field of sciences of cognition, in which psychology, linguistics, and computer science, as well as philosophy and biology, come together to share a common interest, the human mind. Henceforth, memory, language, and processing, rather than just learning, speech, and stimulus–response, have been the key subjects of inquiry in cognitive science.

In line with this evolutionary development, Miller was co-founder, along with J. S. Bruner, of the Harvard Center for Cognitive Studies (1960–1967). The center was a critical counterforce to behaviorism, where, under the influence of N. Chomsky's linguistic mentalism, Miller developed experimental procedures for the study of mental processes underlying grammar. In the late 1960s he turned his interest from grammar to semantics, and the mental lexicon has been his abiding research interest ever since, beginning at the Princeton Institute of Advanced Study. Later, in collaboration with G. Harman, he established the Princeton Cognitive Science Laboratory (1986), where he has been principal investigator of WordNet, an evolving online English lexical reference system designed under psycholinguistic theories of human lexical memory. He was also Director of the McDonnell-Pew Program in Cognitive Neuroscience (1989–1994).

Milroy, Lesley

M Newman, Queens College/CUNY, Flushing, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Leslie Milroy – her full name is actually Ann Leslie Milroy – is, as of 2004–2005, professor and chair of the Linguistics Department at the University of Michigan, where she holds the Hans Kurath Collegiate Chair. Although Milroy has done work on communication disorders (Lesser and Milroy, 1993) and conversation analysis (Wei and Milroy, 1995; Shin and Milroy, 2000), she is best known for her work in sociolinguistics.

Two related characteristics of Milroy's work in this discipline are the broadness of her interests and her ability to make significant contributions in multiple areas. She has produced important works in sociolinguistic methodology (Milroy and Gordon, 2003), language ideology (Milroy, 2001), and bilingualism (Milroy and Muysken, 1995; Wei and Milroy, 1995; Shin and Milroy, 2000). However, the most prominent sociolinguistic contribution Milroy has made, and continues to make, involves language variation and change.

Milroy performed a pioneering study in Belfast on the role of social networks as vehicles for language change processes, and her monograph on that subject (Milroy, 1987) has become a classic. The concept of social network originates in sociology, and Milroy's sociolinguistic use of it in Belfast involved an analysis along two dimensions: the amount of contact with

upon him are Member of the American Academy of Arts and Sciences (1957), Member of the National Academy of Sciences (1962), Foreign Member of the Royal Netherlands Academy of Arts and Sciences (1985), American Psychological Foundation's Life Achievement Award (1990), and National Medal of Science (1991).

Leslie Milroy – her full name is actually Ann Leslie Milroy – is, as of 2004–2005, professor and chair of the Linguistics Department at the University of Michigan, where she holds the Hans Kurath Collegiate Chair. Although Milroy has done work on communication disorders (Lesser and Milroy, 1993) and conversation analysis (Wei and Milroy, 1995; Shin and Milroy, 2000), she is best known for her work in sociolinguistics.

Two related characteristics of Milroy's work in this discipline are the broadness of her interests and her ability to make significant contributions in multiple areas. She has produced important works in sociolinguistic methodology (Milroy and Gordon, 2003), language ideology (Milroy, 2001), and bilingualism (Milroy and Muysken, 1995; Wei and Milroy, 1995; Shin and Milroy, 2000). However, the most prominent sociolinguistic contribution Milroy has made, and continues to make, involves language variation and change.

Milroy performed a pioneering study in Belfast on the role of social networks as vehicles for language change processes, and her monograph on that subject (Milroy, 1987) has become a classic. The concept of social network originates in sociology, and Milroy's sociolinguistic use of it in Belfast involved an analysis along two dimensions: the amount of contact with

other networks and the degree to which members of a single network have contact with each other. A common misunderstanding opposes social network analysis to analysis of macrosocial structure – notably gender, ethnicity, and class – and the symbolic role of linguistic variables in conflicts between such groups. However, in Milroy's Belfast study, social network analysis actually complements and interacts with correlations of variants with macrosocial categories by connecting microsocial structural differences to macrosocial ones. As such it creates a more sophisticated and sociolinguistically plausible analysis than one based solely on macrosocial identity. Milroy is currently continuing her variationist research in Detroit. This project is in a fairly early stage as of this writing, but it has the promise to provide data and theoretical contributions to our understanding of English variation in North America, and particularly the role of ethnicity and race in that variation.

Another important contribution Milroy has made involves language prescription and the origin and maintenance of standard language varieties. Together with her husband, James Milroy, she undertook one of only a very few studies of this important sociolinguistic phenomenon. Their book, *Authority in language: investigating standard English*, was the first major work to explore prescription as an ideology of language and to establish the linguistic characteristics of standard languages, in particular the suppression of variation among linguistic forms. The impact of this work can be seen in the fact that the book has been reissued in three editions (Milroy and Milroy, 1985 [1991, 1999]). Leslie Milroy has had an important career in sociolinguistics and a number of related areas. She is one of the few sociolinguists who have managed to make important contributions across a number of subfields.

Mind Style

E Semino, Bowland College, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Definition and Scope

The notion of mind style was introduced by Fowler (1977, 1986, 1996) in order to capture the way in which distinctive and systematic linguistic patterns in fictional texts may project an individual's characteristic mental habits and view of the (fictional) world:

> We may coin the term 'mind style' to refer to any distinctive linguistic representation of an individual mental self. (Fowler, 1977: 103)

> Cumulatively, consistent structural options, agreeing in cutting the presented world to one pattern or another, give rise to an impression of a world-view, what I shall call a 'mind style.' (Fowler, 1977: 76)

other networks and the degree to which members of a single network have contact with each other. A common misunderstanding opposes social network analysis to analysis of macrosocial structure – notably gender, ethnicity, and class – and the symbolic role of linguistic variables in conflicts between such groups. However, in Milroy's Belfast study, social network analysis actually complements and interacts with correlations of variants with macrosocial categories by connecting microsocial structural differences to macrosocial ones. As such it creates a more sophisticated and sociolinguistically plausible analysis than one based solely on macrosocial identity. Milroy is currently continuing her variationist research in Detroit. This project is in a fairly early stage as of this writing, but it has the promise to provide data and theoretical contributions to our understanding of English variation in North America, and particularly the role of ethnicity and race in that variation.

Another important contribution Milroy has made involves language prescription and the origin and maintenance of standard language varieties. Together with her husband, James Milroy, she undertook one of only a very few studies of this important sociolinguistic phenomenon. Their book, *Authority in language: investigating standard English*, was the first major work to explore prescription as an ideology of language and to establish the linguistic characteristics of standard languages, in particular the suppression of variation among linguistic forms. The impact of this work can be seen in the fact that the book has been reissued in three editions (Milroy and Milroy, 1985 [1991, 1999]). Leslie Milroy has had an important career in sociolinguistics and a number of related areas. She is one of the few sociolinguists who have managed to make important contributions across a number of subfields.

Mind Style

E Semino, Bowland College, Lancaster University, Lancaster, UK

Definition and Scope

The notion of mind style was introduced by Fowler (1977, 1986, 1996) in order to capture the way in which distinctive and systematic linguistic patterns in fictional texts may project an individual's characteristic mental habits and view of the (fictional) world:

> We may coin the term 'mind style' to refer to any distinctive linguistic representation of an individual mental self. (Fowler, 1977: 103)

> Cumulatively, consistent structural options, agreeing in cutting the presented world to one pattern or another, give rise to an impression of a world-view, what I shall call a 'mind style.' (Fowler, 1977: 76)

Building on Fowler's work, Bockting has more recently defined mind style as "the expression in language of the conceptualisation of 'reality' in a particular mind" (Bockting, 1995: 23).

The most famous and influential analysis of mind style, which inspired Fowler's own work, is Halliday's (1971) study of the language of William Golding's novel *The inheritors*. Halliday noted that the part of the novel that conveys the viewpoint of a Neanderthal character called Lok contains few transitive constructions with animate agents, but a relatively high number of inanimate agents. For example, Lok's perception of being shot at with bow and arrow by a stranger is conveyed as follows:

> The stick began to grow shorter at both ends. Then it shot out to full length again.
>
> The dead tree by Lok's ear acquired a voice.
>
> "Clop!" (Golding, 1955: 106)

Halliday concluded that these unusual transitivity patterns reflects Lok's cognitive limitations, and particularly his poor understanding of human agency, cause-effects relationships, and of the distinction between animate and inanimate entities.

The notion of mind style can be applied to authors and narrators, as well as characters. Leech and Short (1981: 191), for example, compare the mind styles of the (implied) authors of three different novels, and Boase-Beier (2003) applies the notion of mind style to the way in which poems reflect the cognitive states of their authors. However, most work in this area has focused on the worldviews of characters in third-person narratives (e.g., Lok in *The inheritors*), or of characters-narrators in first-person narratives (e.g., the Compson brothers in Faulkner's *The sound and the fury*).

As Fowler (1977: 103) originally pointed out, a character, narrator, or author may or may not be (presented as being) consciously aware of the linguistic and cognitive peculiarities that characterize their mind style. We are unlikely to imagine, for example, that Lok is aware of his poor grasp of agency, animacy, and causation. By contrast, the kinds of characteristics that are normally seen as constituting a mind style tend to be fairly permanent traits, which may either not change in the course of a novel, or change very gradually. Lok's understanding of his world, for example, changes very little in the course of *The inheritors* (see Black, 1993), whereas the mind style of Clegg in Fowles's *The collector* does not seem to change at all (see Semino, 2002; see also Boase-Beier, 2003, for the view that the concept of mind style should be extended to the expression of transient cognitive states).

Fowler presents the notion of mind style as equivalent to that of "point of view on the ideological plane" (Fowler, 1986: 15). In contrast, Semino and Swindlehurst (1996) and Semino (2002) have proposed that these two notions can be applied to different *aspects* of worldviews. They suggest that ideological point of view is most apt to capture the elements of worldviews that are "social, cultural, religious or political in origin" and that individuals share "with others belonging to similar social, cultural, religious or political groups" (Semino, 2002: 97); mind style, by contrast, best captures the elements of world views that are mostly "personal and cognitive in origin" (Semino, 2002: 97), and that may be entirely idiosyncratic, or shared by people with the same cognitive habits or limitations, such as young children or sufferers from a particular type of mental condition. Clearly, however, these different aspects overlap and interact within individual worldviews.

Linguistic Patterns and Mind Style

The application of the notion of mind style requires two interrelated analytical steps, namely, the identification in a text (or part of a text) of linguistic patterns that are distinctive and systematic, and the interpretation of these patterns as the reflection of the characteristic, often idiosyncratic, workings of an individual's mind. Both analytical steps can be problematic, however.

The identification of distinctive and systematic linguistic patterns can be aided by quantitative analysis and comparison, as showed in Halliday's (1971: 342–343) study of *The inheritors* and some of Fowler's analyses (e.g., Fowler, 1986: 165–167). Hoover's (1999) more recent work on *The inheritors* shows the potential contribution of corpus-based analytical techniques. His machine-aided comparison of the text of *The inheritors* with several different corpora arrives at a more fine-grained and reliable account than Halliday's of what exactly characterizes the "Lok-language" in the novel (see Hoover, 1999: 155). By contrast, however, interpretative significance cannot be straightforwardly correlated with frequency. For example, in Semino (2002). I have claimed that Clegg's mind style in *The collector* is characterized in part by the metaphorical construction of women as butterflies, even though Clegg's narrative in the novel contains less than fifteen examples of this metaphor. However, Clegg's descriptions of women as butterflies are very unusual, highly elaborated, and intimately related with Clegg's life and habits (he is a passionate, almost obsessive, butterfly collector). All this (as well as the title of the novel itself) can be regarded as evidence for the fact that the metaphorical conceptualization of women as butterflies is an important feature of Clegg's mind style.

The interpretation of linguistic patterns in terms of mind style relies on the assumption that *linguistic* behaviors and habits reflect *cognitive* behavior and habits, or, in other words, that the way we speak reflects the way we think. This involves a weak version of the Whorfian hypothesis that the language we speak both reflects and determines our thinking. In this respect, however, Halliday (1971: 333) points out that "[t]he speaker can see through and around the settings of his semantic system" and Fowler (1986: 149) adds that "[a] language embodies ways, not *one* way, of looking at the world," so that "speakers are not going to be trapped within one overriding system of beliefs." With fictional characters, in any case, claims about mind style are sometimes made on the basis of the (verbal) representations of thought, which is legitimized by the special conventions of fictional discourse. The issue remains, however, that what exactly we infer from an individual's language, or represented thoughts, about their worldview or mental habits is a matter of interpretation (see, for example, Fish's 1981 critique of Halliday's interpretation of *The inheritors*). Bockting (1994, 1995) tackles this issue by explicitly drawing from psychoanalysis and psychiatry in order to interpret the narratives of the Compson brothers in *The sound and the fury* as indicative of different types of mental illness.

A large variety of linguistic phenomena and patterns have been linked, in different studies, to the projection of mind style. As far as characters are concerned, these patterns may be found in the representation of speech, thought, and internal point of view more generally. In the case of authors and narrators, any part of a text or narrative may be evocative of mind style. Fowler usefully distinguishes between linguistic devices that "make explicit (though sometimes ironic) *announcements* of beliefs" (e.g., modal verbs), and linguistic phenomena that "indirectly, but nevertheless convincingly, may be *symptomatic* of world-view" (Fowler, 1986: 132, emphasis in original). Not surprisingly, it is the latter type of devices that have received the greatest attention, as I will show below. Although, for the sake of exposition, I discuss each relevant linguistic phenomenon in turn, it is important to bear in mind that it is normally the interaction of different types of linguistic patterns in a particular context that results in the perception of a particular mind style.

Transitivity

Halliday's claims about Lok's worldview are mostly based on patterns of transitivity, namely on how processes, participants and circumstances are expressed at the level of the clause. In his corpus-based study of *The inheritors*, Hoover (1999) found more specifically that the section of the novel that reflects Lok's worldview is characterized by the use of "body parts and inanimate objects as agents, and as subjects of mental process and perception verbs, and intransitive verbs of motion," and by "body parts and inanimate objects with attributes normally associated with animate beings" (e.g., "Lok's feet were clever. They saw." Golding, 1955: 11) (Hoover, 1999: 155).

A number of studies have identified unusual transitivity patterns in other novels, and have analyzed them as a reflection of idiosyncratic worldviews. In the case of Faulkner's *The sound and the fury*, the low frequency of transitive structures and human agents in Benji Compson's narrative has been interpreted (alongside other lexical and grammatical peculiarities) as a reflection of Benji's limited understanding of causation and human actions, which results from his mental retardation: Benji is normally described as an adult with the mind of a small child (Bockting, 1995: 43ff.; Fowler, 1986: 133; Leech and Short, 1981: 202ff.).

A particularly interesting phenomenon is the use of normally transitive verbs as intransitives. In *The sound and the fury*, Benji's unwitting description of a game of golf contains sentences such as "he hit and the other hit," and "Luster threw" (Faulkner, 1987: 3). Similarly, in Kesey's *One flew over the cuckoo's nest*, Bromden, the first-person narrator (who is a patient in a mental hospital), uses the verb 'hate' as an intransitive verb, as in "When they hate like this" (Kesey, 1973: 9). In both cases, readers may infer that the character in question has a limited understanding of basic activities and reactions: Benji does not understand the motives and goals of the actions he is observing, and Bromden has difficulties relating to people's emotional states and responses (Bockting, 1995: 45; Fowler, 1986: 133; Leech and Short, 1981: 206; Semino and Swindlehurst, 1996: 151). In contrast, the frequent attribution of human actions and characteristics to inanimate entities in Gothic novels has been interpreted by Fowler as contributing to evoke the morbid mind style of characters who perceive their surroundings as disturbing and menacingly active (Fowler, 1986: 158ff.).

Grammatical Structure

The length and structure of sentences often has been seen as an indication of the degree of sophistication of the projected worldview. More specifically, the use of short, simple sentences can, in conjunction with other linguistic markers of 'simplicity,' contribute to evoke the mind style of a child, or of a childlike adult. Many of the sentences in Benji's narrative in *The sound and the fury* are relatively short, and have simple grammatical structures (e.g., "He hit"

and "I held to the fence," Faulkner, 1987: 3) (see Bockting, 1995: 44; Leech and Short, 1981: 205–206). Similarly, the projection of the world view of Stephen Dedalus as a child in Joyce's *A portrait of the artist as a young man* partly results from the use of short, simple sentences, such as "He sang that song. That was his song" (Joyce, 1977: 9). In the relevant parts of these novels, longer, more complex sentences tend to involve co-ordination (usually via 'and') rather than subordination, as in the following extract from Benji Compson's narrative: "Then they put the flag back and they went to the table, and he hit and the other hit" (Faulkner, 1987: 3) (see Bockting, 1995: 44; Leech and Short, 1981: 205–206). Lennie, the mentally retarded co-protagonist of Steinbeck's *Of mice and men*, also tends to alternate, in his speech, between short simple sentences and longer paratactic sentences, as in "We gonna have a house an' a garden and a place for alfalfa, an' that alfalfa is for the rabbits, an' I take a sack and get it all fulla alfalfa and then I take it to the rabbits" (Steinbeck, 1992: 94).

The interpretation of such patterns as indicative of childlike mind styles partly relies on parallels with the language typical of young children, and assumes a connection between degree of grammatical complexity and degree of cognitive sophistication. However, the use of short, simple sentences can only convey simplicity of mind when it cooccurs with certain other phenomena, such as the transitivity patterns I mentioned earlier and some of the lexical patterns I will mention next.

Lexis

Vocabulary choices are perhaps the most salient and versatile technique for the projection of mind style. It has been noted, for example, that the vocabulary of Benji's narrative is relatively restricted and repetitive, and mostly consists of short words denoting concrete concepts. This contributes to suggest his rather limited experience and understanding of the world (Bockting, 1995: 43, Leech and Short, 1981: 204–205).

As Fowler (1986: 151ff.) makes clear, the study of mind style relies on the assumption that an individual's lexical repertoire reflects their conceptual repertoire: generally speaking, the availability of a particular lexical item suggests access to the relevant concept, while gaps in vocabulary suggest lack of (or limited) access to the relevant concepts. Another fundamental assumption concerns the notion of an average, adult lexical repertoire, which includes, for example, items such as 'arrow' and 'parachute' but does not include more specialized terms such as 'complementiser' or 'Fritillaries.'

Most studies of mind style have focused on examples that involve 'underlexicalization,' namely the absence of common vocabulary items from an individual's lexical repertoire (Fowler, 1986: 152). In the section of *The inheritors* that presents Lok's point of view, as we have seen, the word "stick" is used where we would normally use 'bow,' whereas "twig" is used in place of 'arrow.' Similarly, in *The sound and the fury*, Benji uses 'table' in place of the golfing term 'tee.' In Fowler's (1986: 152) terms, here we have the suppression of lexical items from the relevant area of experience (e.g., a particular type of warfare, golf, etc.), and the substitution of these lexical items with simpler, less specific words or paraphrases. Underlexicalization, therefore, often results in what Bockting (1995: 43) calls "overgeneralization," namely, the use of more general lexical items where more specific ones would be more appropriate and expected. This may not only suggest that a character lacks a particular word and concept but also that they have simplistically assimilated a member of a new category into an existing, but inappropriate, category (e.g., Lok does not seem to realize that what are referred to as "stick" and "twig" are weapons).

A slightly different type of substitution is involved when, in Louis de Bernières *Captain Corelli's mandolin*, the sight of a man floating down from a parachute is described as follows: "A sort of white mushroom was drifting down with a tiny man suspended underneath" (de Bernières, 1999: 333). The relevant section of the novel reflects the viewpoint of a rather simple-minded shepherd called Alekos, who is suddenly confronted with examples of modern warfare during World War II. From his point of view, a parachute is therefore referred to as "a mushroom," and hand grenades as "heavy khaki-colored iron pine cones with metal levers" (de Bernières, 1999: 335). Here, the terms that substitute for the missing vocabulary items are not more general but, rather, belong to a different domain of experience with which the relevant character is more familiar, namely nature. Such examples can therefore be interpreted as metaphors based on a visual similarity between the relevant, unknown, entity and another, familiar, entity (see Semino, 2002: 103). Other examples of this kind of substitution, however, seem to suggest misinterpretation on the part of the relevant character: Alekos, for example, does seem to know that the "mushroom" and the "pine cones" are not actual instances of mushrooms and pine cones, but mistakenly regards the man landing with the "white mushroom" as an angel, and continues to hold this belief even after he has been presented with ample evidence to the contrary. As Black (1993) points out in relation to Lok in *The inheritors*, it is sometimes difficult to decide

whether to read a particular lexical choice as a metaphorical expression or as an instance of mistaken categorization. In some cases, it is indeed possible to conclude that a particular expression reflects a literal belief on the part of the character, while simultaneously providing an apt metaphorical description for the readers (e.g., when Lok's feet are described as "clever").

The opposite of underlexicalization, 'overlexicalization,' also can be used to evoke mind style. Fowler (1986: 155–156) shows how a profusion of terms to do with nature, fruit, and ripeness contributes to the worldview projected by Keats's poem '*To autumn*.' Semino and Swindlehurst (1996) show how in *One flew over the cuckoo's nest*, Bromden is underlexicalized in the area of human emotions, but overlexicalized in the areas of machines and technology. Similarly, Clegg's passion for butterflies in Fowles's *The collector* is partly conveyed by his use of technical expressions from the field of lepidoptery, such as "sporadic," "Mazarine blue" and "Queen of Spain Fritillary" (see Semino, 2002). The 15-year-old autistic narrator in Mark Haddon's *The curious incident of the dog in the night-time* has an exceptional mathematical talent, which is reflected in his use of complicated graphs and formulae, and of technical vocabulary as in "λ is what is called a constant" (Haddon, 2003: 127). In all such cases, a character's above-average expertise in a particular field is combined with deficiencies in other areas, and the resulting mind style is central to the development of the plot.

Figurative Language

A powerful device for the evocation of mind style is the use of systematic but unconventional figurative patterns, which, following recent research on metaphor (Lakoff and Johnson, 1980: Lakoff and Turner, 1989), can be interpreted as reflecting idiosyncratic ways of thinking. In fact, some of the transitivity patterns that I discussed earlier can be seen as unusually frequent and creative uses of personification. This applies particularly to the frequent occurrence of inanimate subjects for verbs requiring animate agents in the language that reflects the worldviews of Lok in *The inheritors* (Black, 1993; Halliday, 1971), Benji in *The sound and the fury* (Bockting, 1995; Fowler, 1986; Leech and Short, 1981), and the characters of some Gothic novels (Fowler, 1986).

In the case of personification, the relevant metaphorical source domain (i.e., knowledge about people) is equally familiar and available to human beings generally. In other cases, an area of experience with which a character has particular familiarity can function as the source domain for systematic but idiosyncratic metaphorical patterns in (part of) a literary work. Bromden (the first-person narrator in Kesey's *One flew over the cuckoo's nest*) is an expert electrician, but he has a rather deficient understanding of his world, and especially of people and their emotions. Semino and Swindlehurst (1996) note that Bromden's narrative shows an unusually high frequency of highly creative metaphors and similes drawing from the source domain of machinery. Fo example, he describes society as the "Combine," the hospital ward where he lives as a "factory for the Combine [. . .] for fixing up mistakes made in the neighborhoods and in the schools and in the churches" (Kesey, 1973: 36), the nurse who runs the ward as being "like a watchful robot" (Kesey, 1973: 27) or "quiet as an electric alarm about to go off" (Kesey, 1973: 44), and the category of patients he belongs to (the "Chronics") as "machines with flaws inside that can't be repaired" (Kesey, 1973: 17). Semino and Swindlehurst (1996) argue that Bromden compensates for some of his cognitive limitations by drawing from the domain of experience most familiar to him, namely machinery. This leads to an alienated and mechanistic worldview, particularly because, at times, Bromden appears to believe that people and society really are machines, rather than simply machinelike.

Similarly, in Semino (2002), I have shown that, in Fowles's *The collector*, Frederick Clegg often talks and thinks about women in terms of metaphors drawn from his favorite area of experience, lepidoptery. For example, he describes the hair of the woman he is infatuated with, Miranda, as "very pale, silky, like burnet cocoons" (Fowles, 1998: 9), and a prostitute he fails to have sex with as "a specimen you would turn away from, out collecting" (Fowles, 1998: 15). When he suddenly becomes rich, he kidnaps Miranda much as he would collect a butterfly, and attempts to keep her captive so that he can enjoy watching her, rather like he enjoys looking at the butterflies in his collection. As with Bromden, Clegg's worldview is unusually reliant on a particular area of experience which functions as a particularly productive metaphorical source domain. However, in both cases the characters are deficient in other areas (Bromden has some form of mental illness, Clegg has difficulties with socialization and sex, and finally behaves like a psychopath), and this ultimately results in the impression of minds that are deeply disturbed, albeit in different ways and with different outcomes in the plots of the two novels. As Semino and Swindlehurst put it, consistent but idiosyncratic metaphorical patterns may be interpreted as a reflection of "an idiosyncratic cognitive habit, a personal way of making sense of and talking about the world: in other words, a particular mind style" (Semino and Swindlehurst, 1996: 147). In contrast, in *The curious incident of the dog in the night-time*, Chris Boone,

who has Asperger's syndrome, candidly and lucidly explains that he does not understand common metaphorical expressions such as "He was the apple of her eye" and "The dog was stone dead" (Haddon, 2003: 19). Although, inevitably, his first-person narrative is not entirely consistent, it is indeed largely devoid of metaphorical expressions of this kind.

Other Phenomena

A number of further linguistic phenomena can contribute to the evocation of mind style. Fowler (1986: 160) includes the frequent use of negation and paradox among the linguistic triggers of the peculiar worldview of a Gothic novel. Both Fowler (1986: 134) and Bockting (1995: 46–47) mention unusual choices in referential expressions and deixis as contributing to Benji's mind style in *The sound and the fury*. Bockting (1995) also notices how each of the Compson brothers in *The sound and the fury* has an unusual way of reporting others' (or their own) words, and shows how this combines with other aspects of their linguistic behavior to suggest different types of mental illness.

Some studies have pointed out how apparently factual descriptions of contextually implausible events can contribute to the presentation of abnormal mind styles. In *The sound and the fury*, Benji describes what appears to be a dizziness attack as an external event: "The ground kept sloping up [...] Then the barn wasn't there and we had to wait until it came back" (Faulkner, 1987: 23–24) (Bockting, 1995: 53). In *One flew over the cuckoo's nest*, Bromden states that the hospital staff regularly switch on a "fog machine," which renders him unable to see and hear other people properly but also makes him feel unusually safe. Readers, however, are likely to interpret this as an indication that Bromden suffers from intermittent episodes of loss of consciousness and disorientiation (see Semino and Swindlehurst, 1996).

A useful area for further exploration is to do with the ways in which characters communicate with other characters in dialogue, or the ways in which narrators communicate information about the fictional world to their audience or addressees. A particularly interesting case is Chris Boone in Haddon's *The curious incident of the dog in the night-time*. The fact that Chris has Asperger's syndrome explains why he does not like to be touched, has a whole range of apparently nonsensical fixations (e.g., he refuses to touch yellow or brown things), finds it difficult to understand people's emotional reactions, starts groaning when upset, and so on. In addition, as I have already said, Chris cannot understand the kinds of metaphorical expressions that have nonsensical literal meanings (e.g., "We had a real pig of a day") because, as he puts it, they are "lies" (Haddon, 2003: 20). Similarly, he is unable to lie himself, even when a lie would be advantageous and socially acceptable. For example, early in the novel he is arrested for hitting a policeman who had touched his arm while questioning him. When he is later told that he is being released because his attack on the policeman was "an accident," Chris replies, "But it wasn't an accident" (Haddon, 2003: 23). In Grice's (1975) terms, Chris is unable to break the maxim of quality ("Do not say what you believe to be false"): he can neither violate the maxim (i.e., lie), nor flout it (i.e., say something that is patently untrue in order to generate an implicature, as is the case with some metaphorical expressions). He also cannot relate to the fact that others might violate or flout the maxim of quality themselves.

Conversely, Chris constantly infringes Grice's maxim of quantity ("Give the right amount of information"), i.e., he breaks it without intending to do so. Because he has an obsessive attitude to detail, he constantly provides too much information, both as a narrator and as a character. In his narration, he regularly gives to-the-minute time updates even when they are not relevant to the plot (e.g., "It was 1:12 am," Haddon, 2003: 21), and describes in minute detail the most trivial events and actions (e.g., how many pellets of food for his pet mouse he has in his pocket). Similarly, in conversation with other characters, he either provides too much or too little detail. At the beginning of the novel, the police are called to investigate the death of a neighbor's dog, which Chris has found in the next-door garden. When a policeman asks him what is going on, Chris replies, "The dog is dead" (Haddon, 2003: 7), which clearly does not give the policeman any information he did not already have. By contrast, when the policeman asks him how old he is, Chris replies, "I am 15 years and 3 months and 2 days" (Haddon, 2003: 7). Overall, then, Chris's narrative reveals some fairly profound difficulties in managing the exchange of information and communication generally, which can be related to a particular autistic condition, and can be accounted for in terms of Grice's (1975) conversational maxims.

Degrees of Abnormality and Opaqueness in Mind Style

Leech and Short (1981: 189) propose a cline from "natural and uncontrived" mind styles "to those which clearly impose an unorthodox conception of the fictional world." They then go on to discuss some "normal" authorial mind styles as well as some more "unusual" mind styles, such as Benji Compson's. It is indeed possible to compare different mind styles in terms of their degree of distance from what might

be regarded as a normal worldview. For example, Lok's understanding of his world is further removed from the average reader's worldview than the heightened awareness that Fowler (1986: 158ff.) detects in a Gothic novel. The notion of mind style is in any case particularly relevant when the presented world view differs in some noticeable way from the reader's assumed normal or default way of making sense of things. As Leech and Short (1981: 202) point out, it is more likely for character's mind styles to be constructed and perceived as odd, which explains why most studies of mind style focus on characters or first-person narrators.

The evocation of a unusual mind styles may also result in different degrees of opaqueness in the presentation of the fictional world. In some cases, the choice of a particular mind style may confuse first-time readers, even though what is being described is a familiar activity. This applies, for example, to Benji's description of a golf game at the beginning of *The sound and the fury*, and to the description of a stranger shooting an arrow at Lok in *The inheritors*. In other cases, readers can more easily "read through" a character's mistaken understanding, such as when, in *Captain Corelli's mandolin*, we are presented with Alekos's belief that he is being visited by an angel. With Chris in *A curious incident*, in contrast, there is little risk of confusion, but readers will often make inferences about the fictional world that Chris seems unable to make (such as concerning the motives and goals of adults in the story).

It is worth noticing that lexical and grammatical simplicity does not necessarily correlate with ease of reading, but may sometimes contribute to opaqueness. As I have mentioned, the language that conveys Lok's mind style in *The inheritors* is lexically and grammatically simple, but the use of generic lexical items in place of more specific ones makes it difficult for readers to recognize familiar objects and actions (see also Hoover, 1999: 79ff.). It is also worth mentioning, in conclusion, that describing a mind style as unusual or limited does not necessarily involve a negative evaluation: as many studies have pointed out, the worldviews of characters such as Benji or Bromden often result in highly poetic and insightful images, partly because the relevant characters often have an innocent, fresh perspective on things, unconstrained by the conventions and preconceptions that result from what might be called 'normality.'

Minimalism

H Lasnik, University of Maryland, College Park, MD, USA

The Immediate Antecedents of the Minimalist Program

Minimalism is the most recent instantiation of transformational generative grammar. The fundamental idea continues to be that a sentence is the result of a computation producing a derivation, beginning with an abstract structural representation sequentially altered by structure-dependent transformations. The Minimalist program maintains that these derivations and representations conform to an economy criterion that demands that they be minimal in a sense determined by the language faculty (perhaps ultimately by general properties of organic systems): no extra steps in derivations and no extra symbols in representations, and no representations beyond those that are necessary for the system to function at all in connecting sound (or, in the case of signed languages, gesture) and meaning.

Minimalism, as articulated by Noam Chomsky, can best be understood against the background of its immediate predecessor, called Government-Binding (GB) or the Principles and Parameters model. In that model, there are four significant levels of representation, related by derivation as in Figure 1.

The deep structure (D-structure) is constructed based on the thematic (θ) relations of the predicates and arguments that will occur in the sentence. Transformations alter this D-structure representation, movement transformations displacing subunits of structure leaving traces marking the positions from which the movement took place, eventually producing a surface structure (S-structure). For instance, in a wh-interrogative sentence such as (1), the auxiliary verb *are* is moved to a position preceding the subject *you*, and the wh-interrogative word *what* is moved to initial position (t indicates a trace).

(1) what are you t_{are} talking about t_{what}?

Transformations of the same character continue the derivation to the logical form (LF), the interface with the conceptual-intentional system of the mind. The rules of the phonological component continue the derivation from S-structure to the phonetic form (PF), the interface with the articulatory-perceptual system. The portion of the derivation between the D-structure and S-structure is often called 'overt syntax'; that between the S-structure and LF is called 'covert syntax' because operations in that portion of the derivation have no observable phonetic effects, given the organization in Figure 1. Under the traditional view that a human language is a way of relating sound and meaning, the interface levels PF and LF were assumed to be ineliminable. Minimalism begins with the position that these levels of representation are the only levels. Eventually, as discussed later, in a certain sense even these levels are eliminated. This kind of argument is characteristic of Minimalism, which differs in several technical ways from its predecessor and which also differs in perspective. Early work in transformational grammar concentrated heavily on descriptive adequacy, that is, on the task of formulating grammars that correctly describe the intrinsic competence of the idealized native speaker. Beginning with Chomsky (1965), the focus began to shift toward explanatory adequacy, the formulation of models of linguistic theory that show how the child can succeed in selecting a descriptively adequate grammar on the basis of primary linguistic data. This was the central concern of the GB program, instantiated in terms of principles (universal properties argued to be innately given by the human language faculty) and parameters (limited options set by the language learner based on simple readily available data). Minimalism, too, is a principles and parameters approach, but one that aims to move even beyond explanatory adequacy by raising the question of why the language faculty has just the properties it has, given that alternative organizations of the computational system can easily be imagined that also provide good solutions to the puzzle of how children acquire their language so quickly and easily.

Structure Building

Minimalism, in a partial return to the technical apparatus of pre–1965 transformational theory, has no level of D-structure. Rather, lexical items are inserted 'online' in the course of the syntactic derivation. The derivation proceeds cyclically with the most deeply embedded structural unit created first, then combined with the head of which it is the complement to create a larger unit, and so on, all in accord with X'-theory. For example, in the derivation of a simple sentence such as *the woman will see the man*, the noun (N)

man is combined with the determiner (D) *the* to form the determiner phrase (DP) *the man*. This DP then combines with the verb *see* to produce an intermediate projection traditionally labeled V', V-bar (although recent work assumes that such intermediate-category labels have no significance). The DP *the woman* is created in the same fashion as *the man* and is combined with the V' to produce the VP (assuming the VP-internal subject hypothesis, under which the subject, along with the other arguments of a verb, is initially introduced into the structure inside VP). Next, this VP merges with the Tense/Inflectional element *will,* producing I'. The DP *the woman* finally moves to the specifier position of I', yielding the full clausal projection IP (sentence), schematically illustrated here (with some details suppressed) as a phrase structure tree in Figure 2 and as labeled bracketing in example (2).

(2) $[_{IP}$ $[_{DP}$ the woman$]$ $[_{I'}$will $[_{VP}$ *t* $[_{V'}$ see $[_{DP}$ the man$]]]]]$

In a more complex sentence such as *you think the woman will see the man*, the derivation of the embedded sentence is exactly as just outlined. The results of that derivation are then combined with the matrix verb *think*, forming a V', which then combines with *you*, and so on. The processes that merge independent units into new combined structures (generalized transformations) are intermingled with those manipulating existing structures (singulary transformations). There is thus no **one** representation following all lexical insertion and preceding all (singulary) transformations. That is, there is no D-structure.

Some Minimalist Goals

The constraint that derivations proceed strictly monotonically, from the bottom up, had been introduced, along with D-structure, in the standard theory of Chomsky (1965). Chomsky argued that this requirement of cyclicity explains the absence of certain kinds of derivations in language. This was presented at the time as an argument against generalized transformations and for D-structure. But it was cyclicity, rather than D-structure, that was crucial in the account. Minimalism rejects D-structure, reinstates generalized transformations, and preserves cyclicity, still ruling out the kind of anticyclic derivations that were the original concern. The Minimalist version of the cyclic principle, the Extension Condition, demands that both the movement of material already in the structure (singulary transformation) and the merger of a lexical item not yet in the structure (generalized transformation) target the top of the existing tree. Further, in accord with Minimalist precepts, we should seek a deep reason for any constraint we find. In this instance, the idea is that derivations conform to a condition demanding as little tampering as possible with existing structure. When a transformation targets the top of a tree, that tree still exists as a subtree of the new one. On the other hand, when a transformation targets some lower position in the tree, the original tree (such as the one in Figure 3) is itself altered. These two kinds of derivation are schematically displayed in Figures 4 and 5, where Figure 4 involves adjunction of β at the top of Figure 3 and Figure 5 has β adjoined at the bottom of Figure 3.

Some other constraints on the operation of transformations are argued to follow from general principles of economy of derivation. Derivations beginning from the same lexical choices (the numeration, in Chomsky's term) are compared in terms of number of steps, length of movements, and so on, with the less economical ones being rejected (although this raises certain questions of computational complexity,

Figure 2 Phrase tree structure.

Figure 3 Original tree.

Figure 4 Derivation 1: Adjunction of β at top of tree in Figure 3.

Figure 5 Derivation 2: Adjunction of β at bottom of tree in Figure 3.

Figure 6 Tree structure for wh-movement.

discussed later). An example is the Minimalist deduction of the original Superiority Condition, which demands that when multiple items are available for wh-movement in a language, such as English, that allows only one to move, it is the highest one that will be chosen:

(3) who *t* will read what?

(4) *what will who read *t*?

(* indicates unacceptability.) Economy, in the form of Shortest Move, selects (3) over (4) because the sentence-initial interrogative complementizer position needs a wh-expression and the subject is closer to that target of wh-movement than the object is, as can be seen in Figure 6, where C is Complementizer (sentence introducer).

This analysis, like many Minimalist analyses of transformation application, assumes that lexical items are composed of features, some of which need to be checked in particular configurations. This is what drives movement because, all else being equal, a derivation with an instance of movement is less economical than one without. Many of the movement constraints that fall under the Relativized Minimality (RM) constraint are susceptible to an analysis similar to the analysis of Superiority effects. RM, which had an important impact on the developing Minimalist program, forbids movement to a position of a certain type (head position, A(rgument type)-position, A'(non-A)-position) across an intervening position of the same type. Within the Minimalist approach, the effects of this constraint are taken to fall under general economy constraints on derivation.

The simplifying developments in the theory leading toward the Minimalist approach generally led to greater breadth and depth of understanding of both how human languages are organized and how they are acquired by children. This success led Chomsky to put forward the audaciously Minimalist conjecture that the human language faculty might be a computationally 'perfect' solution to the problem of relating sound and meaning, the minimal computational system given the boundary conditions provided by other modules of the mind. This conjecture leads to a general Minimalist critique of syntactic theorizing, including in particular much of Chomsky's own earlier theorizing. Consider, first, the leading idea that multiple derivations from the same initial set of lexical choices are compared, the most economical one being chosen and all the others rejected. This introduces considerable complexity into the computation, especially as the number of alternative derivations multiplies. It thus becomes desirable, even necessary, to develop a model in which all relevant derivational decisions can be made online. At each step, the very next successful step can be determined and determined easily. This arguably more tractable local economy model is suggested by Chomsky (1995a), developed in detail by Collins (1997), and then fully adopted by Chomsky (2000).

The Last-Resort Nature of Syntactic Movement

One major Minimalist concern involves the driving force for syntactic movement. From its inception in the early 1990s, Minimalism has insisted on the last-resort nature of movement: in line with the leading idea of economy, movement must happen for a reason and, in particular, a formal reason. The Case Filter, roughly the requirement that every nominal expression appear by the end of the derivation in a position appropriate to its Case (nominative, accusative, etc.), which was a central component of the GB system, was thought to provide one such driving force. A standard example involves subject raising, an instance of movement proposed in one form or another from the earliest days of transformational generative grammar. This operation captures the thematic relatedness in pairs of examples such as the following:

(5) Mary is certain to win the race

(6) it is certain that Mary will win the race

In (5), as in (6), *Mary* is the understood subject of *win the race*. This fact is captured by deriving (5) from an underlying structure like that of (6), except with an infinitival embedded sentence instead of a finite one:

(7) __ is certain [Mary to win the race]

Crucially, *Mary* in (7) is not in a position appropriate to any Case, as evidenced by parallel examples with pronouns (the only nominal expressions in English overtly displaying a range of Case realizations):

(8) *it is certain [she to fail the exam]

(9) *it is certain [her to fail the exam]

By raising to the higher subject position, the thematic subject of the lower clause can rectify its Case theoretic inadequacy, because, in this instance, the raised position is one licensing the nominative Case:

(10) she is certain [*t* to fail the exam]

But notice that, if the Case requirement of *Mary*/*she* provides the driving force for movement, the requirement will not be satisfied immediately upon the introduction of that nominal expression into the structure. Rather, satisfaction must wait until the next cycle, or, in fact, until an unlimited number of cycles later, because raising configurations can iterate, and it is only the ultimate landing site that licenses nominative Case:

(11) Mary seems to be likely to win the race

(12) Mary is believed to seem to be likely to win the race

A Minimalist critique favors an alternative in which the driving force for movement can be satisfied immediately rather than indefinitely later in the derivation. In the present instance, suppose the crucial inadequacy lies not in the nominal expression but rather in the item that licenses its Case, say the Tense/Inflection head of the clause. That is, Tense has a feature that must be checked against the NP. Then, as soon as that head has been introduced into the structure by generalized transformation, it can attract the NP that will check (and consequently delete) its feature. Movement is then seen from the point of view of the target rather than the moving item itself. The Case of the NP apparently does get checked as a result of the movement, but that is simply a beneficial side effect of satisfying the requirement of the attractor. In an elegant metaphor, Uriagereka (1998) likens the attractor to a virus. Immediately upon its introduction into the body, it is dealt with (by the production of antibodies in the case of physical viruses, by movement to check the viral feature in the syntactic instance). The earlier Minimalist approach to the driving force of movement was called 'Greed' by Chomsky. This later one developed from what Lasnik (1995a) called Enlightened Self-Interest. There is still one residue of Greed, however. As discussed by Lasnik (1995b) and Chomsky (2001b), once the Case feature of a nominal expression has been checked, that expression is no longer available for A-movement, either to another Case position or even to a non-Case position:

(13) *John is certain [*t* will fail the exam]

(14) *it is believed [John to be likely [*t* will fail the exam]

The Syntactic Similarity of Languages

One recurrent theme in GB and Minimalist theorizing is that human languages are syntactically much more similar than they appear to be. The standard GB and early Minimalist approach was the proposal that apparent differences result from derivational timing differences among languages. In a language in which the effects of a transformation are phonetically observable, that operation has happened in overt syntax (i.e., before Spell-out, the branch point toward PF). If the effects are not phonetically observable, the operation has happened in covert syntax. Under both circumstances, LF reflects the results of the transformation. For example, the wh-movement operative in English interrogative sentences such as (1) is overt. In many other languages, including Chinese and Japanese, the interrogative expressions seem to remain *in situ*, unmoved. Huang (1981–1982) presented a very influential argument that even in such languages there is movement but that it is covert. Huang's argument was based on his discovery that certain well-established locality constraints on wh-movement also constrain the distribution and interpretation of certain seemingly unmoved wh-expressions in Chinese. This argument laid the groundwork for much GB and Minimalist research. Along similar lines, Chomsky (1991) discussed object shift, a process moving a direct object out of the VP. In Icelandic, for example, it is overt. Chomsky suggested that it happens even in English, but covertly, so that the object 'sounds' as if it is still within VP. Similarly V-raising is overt in virtually all the Romance languages, among many others, and, as argued by Chomsky, is covert in English. Consider the following examples from English and French.

(15a) John often kisses Mary
(15b) *John kisses often Mary

(16a) *Jean souvent embrasse Marie
(16b) Jean embrasse souvent Marie

Recall that under the last-resort concept, movement is driven by a feature needing to be checked. For V-raising, the feature is assumed to be one that resides in Tense/Infl. Now, what about the difference between French and English? Chomsky (1993) proposed that features that drive movement come in two flavors, strong and weak. Although all such features must be checked eventually (i.e., by the end of all LF operations), strong features must be checked specifically before Spell-out. (See Lasnik, 1999b for a comparison of three theories of strong features.) Given the argument presented previously from computational complexity, a strong feature must be checked immediately on its introduction into a structure. Thus, in French

there is a strong feature in Tense forcing overt raising. The corresponding feature in English is weak. This accounts for (16a), (16b), and (15a), leaving just (15b) as mysterious. In that example, overt movement took place even though only covert movement should have been required. Chomsky argued that this state of affairs should be excluded in general and formulated the principle 'Procrastinate,' which disallows overt movement except when it is necessary (i.e., for the satisfaction of a strong feature).

Procrastinate was often called an economy principle, but it was not obvious that it was. Why is delaying an operation until LF more economical than performing it earlier? In part to answer this question and in part to account for the fact that many of the hypothesized instances of covert movement did not have the expected semantic effects (with respect to quantifier scope, anaphora, etc.) that corresponding overt movements had, Chomsky (1995a), followed by Lasnik (1995b), proposed a modified theory of covert movement. The leading idea of this modified theory was that if movement is driven by the need for formal features to be checked, all that should really move is formal features, in particular Case and agreement features. When movement is overt, this will generally not suffice because phonology will not be able to deal with the resulting scattered object. Thus, the entire word or phrase hosting the features moves along with them, an extension of a phenomenon dubbed 'pied piping' by Ross (1986). Because covert movement does not feed into PF, feature movement in the LF component will not necessitate pied piping. Now, if only formal features of an element raise, plausibly the semantic features relevant for such phenomena as scope and anaphora are left behind (along with the phonological features, of course). For such semantic purposes, then, it is as if no movement took place. Further, Procrastinate now would follow from reasonable notions of economy. Delaying a movement until LF means that pied piping will not be necessary; only formal features will have to move. And moving less is more economical than moving more.

Chomsky (2000, 2001b) took this line of reasoning even further, proposing that there is no feature movement. Rather, a process of agreement (potentially at a substantial distance, constrained only by Relativized Minimality) relates the two items that need to be checked against one another. Many of the phenomena that had been analyzed as involving covert movement are reanalyzed as involving no movement at all, just the operation Agree. (However, see Lasnik, 2002, for some evidence that feature movement cannot be entirely dispensed with.) With no feature movement, phrasal movement is not really a matter of pied piping. Instead, it takes place to satisfy the requirement of certain heads (including the Tense/Inflection head) that they have a specifier, in the X-bar theoretic sense. In fact, such a requirement was already formulated in the early GB framework by Chomsky (1981) and, slightly later, dubbed the Extended Projection Principle (EPP) in Chomsky (1982).

Syntactic Interfaces

The precise nature of the connection between the syntactic derivation and semantic and phonological interfaces has been a central research question throughout the history of generative grammar. In the earliest generative model, the interface is the T-marker, which includes all of the syntactic structures created in the course of the derivation. Subsequent models had the following interfaces with semantics:

- The standard theory: D-structure
- Government-Binding (GB): LF (via S-structure)
- Early Minimalism: LF (via an uninterrupted transformational derivation beginning with the numeration)

The Minimalist approach to structure building is much more similar to that of the 1950s than to any of the intervening models, suggesting that interpretation in the Minimalist model also could be more like that in the early model, distributed over many structures. Already in the late 1960s and early 1970s, there were occasional arguments for such a model and for phonological interpretation as well as semantic interpretation. For example, Bresnan (1971) argued that the phonological rule responsible for assigning English sentences their intonation contour applies cyclically, following each cycle of transformations, rather than applying at the end of the entire syntactic derivation. There were similar proposals for semantic phenomena involving scope and anaphora put forward by Jackendoff (1972). Chomsky (2000, 2001a, 2001b) argued for a general instantiation of this distributed approach to phonological and semantic interpretation, based on ideas of Epstein (1999) and of Uriagereka (1999), who called the approach 'Multiple Spell-Out.' Simplifying some, at the end of each cycle (or 'phase' in Chomsky, 2001b) the syntactic structure created thus far is encapsulated and sent off to the interface components for phonological and semantic interpretation. Thus, although there are still what might be called PF and LF components, there are no levels of PF and LF. Epstein argued that such a move represents a conceptual simplification (in the same way that the elimination of D-structure and S-structure does), and both Uriagereka and Chomsky provided some empirical justification. The role of

syntactic derivation, always very important in Chomskian theorizing, becomes even more central on this view because there are no levels of representation at all. Epstein reasoned that the centrality of (asymmetric) c-command (as opposed to one of a whole range of other conceivable geometric relations) in syntax is predicted on this strongly derivational view but not in a more representational theory. As the derivation proceeds, always merging together pairs of items or substructures, sisterhood and domination (transitive closure of motherhood) are the only immediately available primitives. And X (asymmetrically) c-commands Y if and only if Y is dominated by the sister of X.

Multiple Spell-Out effectively deals with a range of reconstruction phenomena, situations in which a moved item behaves for certain interpretive processes as if it had not moved. For example, a reflexive such as *himself* normally requires an antecedent that c-commands it:

(17) John criticized himself

(18) *himself criticized John

But when the reflexive is fronted from a position c-commanded by an antecedent to a position not in that structural relation, the anaphoric connection is nonetheless still available:

(19) himself, John criticized

This possibility follows straightforwardly if anaphora is interpreted prior to movement. However, other examples show that anaphora at least can be interpreted after movement, as in the following acceptable subject raising example, whose source would not license the anaphoric connection:

(20) John seems to himself to be clever

(21) ___ seems to himself [John to be clever]

At least for this class of phenomena, then, Multiple Spell-Out just provides an option.

Chomsky (1993, 1995a) explored another kind of approach to reconstruction, based on a condition that he calls Inclusiveness. This condition demands that a syntactic derivation merely combine elements of the numeration, without creating any new entities. Traces, traditionally conceived as new objects created by movement, violate this condition. Chomsky therefore proposed that a trace of movement is actually a copy of the item that moved rather than a new sort of entity. Interestingly, this is yet another return to much earlier generative approaches (wherein movement was seen as a compound of copying and deletion, as in Ross, 1986). The copy left behind is normally deleted in the phonological component (although, as shown by Bošković, 2001 and Nunes, 2004, under certain circumstances lower copies are pronounced in order to rescue what would otherwise be PF violations), but it could well persist for semantic purposes, such as the licensing of anaphoric connection. Fox (2000) presented an extensive analysis of scope and anaphora reconstruction effects in terms of the copy theory. Lasnik (1999a, 2001) examined the presence and, especially, the absence of certain reconstruction effects with A-movement. For dealing with reconstruction effects, the proper division of labor between Multiple Spell-Out and the copy theory of traces is an important ongoing research topic.

As previously noted, asymmetric c-command is of central importance in Minimalist syntax (as it was, at least implicitly, in the GB framework). A very influential research line, initiated by Kayne (1994), extended the importance of c-command to PF as well. Generative syntax has always been concerned with the hierarchical organization of representations, and the overwhelming majority of syntactically and semantically significant structural relations are hierarchical: domination, immediate domination, c-command, and sisterhood. None of these relations involve linear order, although linear order is obviously manifest in phonological representation. A natural speculation is that linear order is manifest **only** in PF. Kayne's hypothesis is that this comes about via his Linear Correspondence Axiom (LCA), which states that asymmetric c-command is mapped onto PF linear order. This has the far-reaching consequence that structures must always be right-branching, a consequence that is, on the face of it, flagrantly violated in the vast majority of languages. For example, SVO languages such as English are broadly consistent with the requirement, but SOV languages such as Japanese are not. Further, given that movement is always to a c-commanding position, leftward movement is fine but rightward movement is prohibited, contrary to the apparent existence of extraposition-type operations. The antisymmetry approach reanalyzes SOV languages as underlyingly SVO (as all languages must be by this hypothesis) with the SOV order derived by (leftward) movement. Similarly, apparent rightward movement is reanalyzed as a series of leftward movements, many of them remnant movements in which X moves out of Y and then the residual Y moves to a position higher than X. Many phenomena have been productively analyzed in these terms, but one crucial unanswered question at this point is the source of the driving force for all of the required leftward movements.

Phases and Successive Cyclic Movement

Chomsky (1973) first proposed that apparent long movement, as in (22), is actually compounded from a series of short steps.

(22) what does Mary think [that you are talking about *t*]?

Torrego (1984) and McCloskey (1991), among many others, showed how the postulated successive short steps composing a long instance of wh-movement (in interrogatives and/or relative clauses) are overtly marked, for example in Spanish and Irish. In both instances, the marking shows up in or near the complementizer position (via the obligatory fronting of a finite verb or by a change in the form of the complementizer); this is significant in light of Chomsky's proposal that long movement proceeds via (the Specifier of) C. Chomsky (1973) simply stipulated this locality with his Subjacency constraint. At the time, Subjacency represented a notable advance because it unified several disparate locality constraints. However, Minimalism seeks even more – a reason that derivations should work this way. Chomsky (2001b) suggested that when a phase is sent off for semantic and phonological interpretation, its 'edge' (typically a specifier, Spec, position) remains until the next phase and thus is available as an escape hatch. Assuming that CP is a phase, the moving wh-phrase will have to move to the Spec of each CP on the way to its ultimate destination. Phase Impenetrability thus can account for a substantial amount of the locality of movement, and, as seen previously, Relativized Minimality can account for additional instances of locality. Accommodating all island constraints on movement in a Minimalist way is a lively research area.

Conclusion

Minimalism, as Chomsky emphasized, is as yet still just an approach, a conjecture about how human language works (i.e., 'perfectly') and a general program for exploring and developing the conjecture. The explanatory success attained thus far gives some reason for optimism that the approach can be developed into an articulated theory of language.

Introduction

The relationship between minorities and language is complicated. Historically, the problem of minorities is closely related to the development since the 16th century of the modern system of 'nation-states.' The process of state formation, still relevant today, leads to a differentiation between majorities and minorities. It is an inevitable consequence of policies aimed at national homogeneity and cohesion. A distinction has to be made between 'language minorities' and 'minority languages.' The former refers to the social group or community, and the latter to a specific category of languages. Sometimes terms such as 'lesser used,' 'heritage,' 'stateless,' and 'ethnic' language are used in place of 'minority language.' Minority languages are different from majority languages, which are also referred to as 'dominant,' 'national,' or 'state' languages.

There are between 6000 and 7000 different languages in a world of over six billion people. Of all those languages, just a few, such as English or Chinese, are spoken by hundreds of millions of speakers. Most languages are spoken by only a few thousand speakers, or sometimes just a handful of speakers. In fact, 96% of the world's languages are spoken by just 4% of the people. Most of the world's languages are spoken in a broad area on either side of the Equator, in Southeast Asia, India, Africa, and South America. Not all of the 'smaller' languages are minority languages, but most of them are. The theme of minority languages is closely related to 'endangered' or 'threatened' languages, an issue that received increasing attention after Krauss (1992) rang the alarm bell over the future of 90 percent of the world's languages.

Definitions

The concept of 'minority' is problematic from the point of view of several disciplines. What constitutes a minority depends on who defines a minority, and who the beneficiaries are of minority rights. Much work has been done in international law – in lengthy debates and in many forums – concerning minority protection. After World War II, the United Nations expressed a felt need for a clear definition of the concept 'minority.' In particular, the Sub-Commission on the Prevention of Discrimination and the Protection of Minorities became an important agency. Arriving at such a definition took many years, and proved to be a difficult task. Finally, UN Special Rapporteur Capotorti (1979: 7) defined a minority as "a group numerically smaller than the rest of the population of the State to which it belongs and possessing cultural, physical or historical characteristics, a religion or a language different from those of the rest of the population and show, if only implicitly, a sense of solidarity, directed toward preserving their culture, traditions, religion or language."

Although later studies tried to improve on this definition, it still reflects the general understanding of 'minority' in international law (Pentassuglia, 2002: 72), and covers most minority situations (Thompson, 2001: 130). This definition combines 'objective' and 'subjective' approaches which are sometimes seen as

Introduction

The relationship between minorities and language is complicated. Historically, the problem of minorities is closely related to the development since the 16th century of the modern system of 'nation-states.' The process of state formation, still relevant today, leads to a differentiation between majorities and minorities. It is an inevitable consequence of policies aimed at national homogeneity and cohesion. A distinction has to be made between 'language minorities' and 'minority languages.' The former refers to the social group or community, and the latter to a specific category of languages. Sometimes terms such as 'lesser used,' 'heritage,' 'stateless,' and 'ethnic' language are used in place of 'minority language.' Minority languages are different from majority languages, which are also referred to as 'dominant,' 'national,' or 'state' languages.

There are between 6000 and 7000 different languages in a world of over six billion people. Of all those languages, just a few, such as English or Chinese, are spoken by hundreds of millions of speakers. Most languages are spoken by only a few thousand speakers, or sometimes just a handful of speakers. In fact, 96% of the world's languages are spoken by just 4% of the people. Most of the world's languages are spoken in a broad area on either side of the Equator, in Southeast Asia, India, Africa, and South America. Not all of the 'smaller' languages are minority languages, but most of them are. The theme of minority languages is closely related to 'endangered' or 'threatened' languages, an issue that received increasing attention after Krauss (1992) rang the alarm bell over the future of 90 percent of the world's languages.

Definitions

The concept of 'minority' is problematic from the point of view of several disciplines. What constitutes a minority depends on who defines a minority, and who the beneficiaries are of minority rights. Much work has been done in international law – in lengthy debates and in many forums – concerning minority protection. After World War II, the United Nations expressed a felt need for a clear definition of the concept 'minority.' In particular, the Sub-Commission on the Prevention of Discrimination and the Protection of Minorities became an important agency. Arriving at such a definition took many years, and proved to be a difficult task. Finally, UN Special Rapporteur Capotorti (1979: 7) defined a minority as "a group numerically smaller than the rest of the population of the State to which it belongs and possessing cultural, physical or historical characteristics, a religion or a language different from those of the rest of the population and show, if only implicitly, a sense of solidarity, directed toward preserving their culture, traditions, religion or language."

Although later studies tried to improve on this definition, it still reflects the general understanding of 'minority' in international law (Pentassuglia, 2002: 72), and covers most minority situations (Thompson, 2001: 130). This definition combines 'objective' and 'subjective' approaches which are sometimes seen as

contrasting. 'Objective' means that minorities are seen as given historical facts, in which group membership is given or involuntary. In a subjective approach, the free choice and will of the group members are decisive. However, up to the present day, the term 'minority' is not defined in the most important instruments of international law. The reason is that a definition has to serve certain ideological or political goals. Thus it can exclude certain minorities, and as a consequence some can profit from protective measures, where others cannot. In a more sociological sense, the term 'minority' may also be used to refer to less status and less power. In many studies, this usage is given preference over the commonsense understanding wherein 'minority' only refers to sheer numbers ('less than half' or 'a smaller number').

A basic distinction can be made between 'regional minority languages' and 'immigrant minority languages.' The first type are languages that are indigenous and territorial, minorities created during state formation or because of migration of population groups many centuries ago. The second type is the outcome of more recent international migration processes. Still, many examples can be given of how difficult it is to decide whether a language is a minority language or not (Hoffmann, 1991: 219–247). The difficulty in arriving at an acceptable definition lies in the diversity of situations in which minority languages exist.

In recent years, the definition in the European Charter for Regional or Minority Languages (1998) has gained wide acceptance. 'Regional or minority languages' means:

> Languages that are traditionally used within a given territory of a State by nationals of that State who form a group numerically smaller than the rest of the State's population; and different from the official language(s) of that State.

This definition shows the decisive role the nation-state plays in the determination of which language varieties obtain minority rights (and protection), and which do not. The status of a variety as either language or dialect depends primarily on political recognition by a state.

Membership and Numbers

Who belongs to a language minority, and who does not, is not always easy to establish. It does not seem to be possible to give criteria that are valid for all members of a particular group. It is clear that most members of a language minority have certain characteristics in common, but that does not have to be the case for all members. Fundamental criteria for belonging to a language minority are (1) self-categorization, (2) common ancestry, (3) distinctive linguistic, cultural, or historical traits, and (4) a form of social organization that places the language group in a minority position.

These four criteria do not have to be valid for all members of a group, but they do for a large part of them. Self-assignment is a fundamental criterion; categorization by others can also be important, but it is not decisive. Ancestry is usually mixed, and a criterion such as 'linguistic distance' can be extremely complex. A minority can be recognized by the government and obtain provisions or not. Moreover, it is possible to choose to become a member of a minority (by learning the language), or to leave the group (by no longer speaking the language).

Language minorities differ very much in size; there may be only a handful of speakers, or there may be millions. The number of individuals who speak a language seems a simple given, but it does not have to be (Fishman, 1991: 45–46).When drafting a list of minority languages, and the numbers of speakers, one runs inevitably into a lack of consensus on which varieties belong on the list as separate languages, and which may be sub-varieties (Ethnologue, 2004). Counting individuals as speakers is not a straightforward task because there are many different criteria. The most common is mother tongue (i.e., language acquired as a child), but also language competence (the language that someone is able to speak) and main language used (the most important daily means of communication) are considered as criteria. The size of a language minority can therefore differ, depending on whether the mother tongue speakers are counted, or the persons being able to speak a language are included. The speakers of language minorities are counted in different ways; one has to be careful when comparing the sizes of different minorities. All figures are usually estimates.

Analytic Frameworks

Many scholars have presented ideas, models, and theories designed to answer questions related to the conditions under which a shift from minority to majority language takes place, or when a minority language is maintained or revived. Here we can point briefly to a few models, but it is important to mention that a general theory of minority language development is still lacking. These frameworks analyze the relative strength of minorities and the measures necessary for their survival. Often in the past analysts failed to place sufficient emphasis on the social context. The central issue is people, not numbers.

A framework that has gained wide currency in the literature is the ethnolinguistic vitality model (Giles *et al.*, 1977). It is designed as an analytic tool to better assess the position of languages against each other, originally the position of French in Quebec relative to English. The key notion is 'vitality,' which is defined as, "that which makes a group likely to behave as a distinctive and active collective unity in intergroup situations" (Giles *et al.*, 1977: 308). The more vitality a group has, the greater its chances for survival as a distinctive linguistic community. There are three main sets of structural factors that influence the vitality of an ethnolinguistic group: status, demographic, and institutional. The status of a language is dependent upon historical, economic, social, and linguistic factors. Demographic factors have to do with the numbers and distribution of the speakers. Institutional factors concern the position of the language in various sectors of society, such as government, education, mass media, and religion. The stronger the language is on these structural factors, the higher is the ethnolinguistic vitality of the group speaking the language, and the greater are its chances for survival as a linguistic community.

The question can be raised whether an 'objective' account of the position of a (minority) language provided by an expert researcher or a language planner is perceived in the same way by the speakers of the language themselves. For that reason, a 'subjective vitality questionnaire' has been developed to measure the way speakers perceive the vitality of their own and other language groups (Bourhis *et al.*, 1981; Giles and Johnson, 1987).

In 1991, Fishman published his book *Reversing language shift* (RLS) in which he presents a set of ideas for analyzing the situation of (minority) languages around the world. The core of his ideas is formed by the GIDS (Graded Intergenerational Disruption Scale), a kind of scale similar to the one used to measure earthquakes. It establishes the extent to which a language community has been disrupted in the modern world. It is a functional approach where the language is seen to be used for certain functions in society, and not for others. Many threats face minority language communities, and Fishman wants to offer a diagnostic framework in which language planners and language activists can base their strategies to repair the situation, and to prevent further harm from occurring. The GIDS consists of eight stages, from the first and lowest stage where the language community has been broken up and few speakers remain, to the last stage where the language has the highest functions in national media and government. The crucial point is that the family-neighborhood-community nexus has to be secured in order to make certain that a language is transmitted from one generation to the next. Only when that process of intergenerational language transmission is assured, will a language survive.

An innovative combination of the vitality and RLS perspectives is given by Grin (2003; Grin and Moring, 2002) who has constructed a model of language policy for minority languages. Central is a 'policy-to-outcome' path, and the end result is that the minority language is being used to enhance the vitality of the language. In this model three conditions are necessary to reach the goal of minority language use. The first is the *capacity* to use the minority language, in the sense of an adequate degree of linguistic competence, and education is essential for the capacity development of speakers. Second are *opportunities* to use the language, not only in private but also in public. The language policy of the state can play a crucial role in creating opportunities for public language use. Finally, there must be a *desire* to use the language; usually speakers are bilingual, and have a choice to use either the majority language or the minority language. Policy has to improve language attitudes. Together, these three conditions constitute a set of necessary and sufficient conditions for the outcome of language use to appear. This model of capacity, opportunity, and desire must be seen in a 'language ecology' paradigm that stresses the interrelationship between a language and its broader social context (Grin, 2003: 43–48).

Definitions and Purposes

Minority language education is here defined as the school's use of a language (or languages) spoken by students whose heritage language differs from that of the more powerful members of society who usually exercise the most control over state schools. Although minority language education always includes the teaching of the minority language, its main purpose is to educate the minority group by using the heritage language as a cognitive and affective instrument to make sense of their world, and sometimes as a way to improve their mastery of the majority language. Minority language education is most often a component of an education that includes the majority language. Thus, minority language education is more specific and focused than, but usually is a part of, what has been termed bilingual/multilingual education.

Minority language education is important for individuals and groups, especially for the language minority community, but also for the majority community. All quality education builds on strengths, and the greatest strength children entering school possess is the language that they bring from home, the instrument they have used to communicate with others, especially with members of their family, and to make sense of their world. For language minority children, therefore, an education which includes their heritage language has effective benefits, enabling them to find continuity between their first learning context, the home, and the school, and making it possible for them to identify with teachers in ways that build on relationships they have with caregivers and friends. A heritage language education also enables minority children to find themselves in school, in the voices of the books they read, the songs they learn, the stories they weave. In addition, minority language education has sociocognitive benefits, enabling children to use the language they know best

Minority Languages: Education

O García, Columbia University, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Definitions and Purposes

Minority language education is here defined as the school's use of a language (or languages) spoken by students whose heritage language differs from that of the more powerful members of society who usually exercise the most control over state schools. Although minority language education always includes the teaching of the minority language, its main purpose is to educate the minority group by using the heritage language as a cognitive and affective instrument to make sense of their world, and sometimes as a way to improve their mastery of the majority language. Minority language education is most often a component of an education that includes the majority language. Thus, minority language education is more specific and focused than, but usually is a part of, what has been termed bilingual/multilingual education.

Minority language education is important for individuals and groups, especially for the language minority community, but also for the majority community. All quality education builds on strengths, and the greatest strength children entering school possess is the language that they bring from home, the instrument they have used to communicate with others, especially with members of their family, and to make sense of their world. For language minority children, therefore, an education which includes their heritage language has effective benefits, enabling them to find continuity between their first learning context, the home, and the school, and making it possible for them to identify with teachers in ways that build on relationships they have with caregivers and friends. A heritage language education also enables minority children to find themselves in school, in the voices of the books they read, the songs they learn, the stories they weave. In addition, minority language education has sociocognitive benefits, enabling children to use the language they know best

to develop their understanding of cognitively complex academic material (Baker and Jones, 1998; Cummins, 2000; Baker, 2001). With time, and alongside a quality education in the majority language, a minority language education enables students to reap some of the sociocognitive benefits that have been associated with bilingualism – greater metalinguistic awareness and divergent thinking (Bialystok, 2001).

In society, minority language education is important for both the minority group and the majority group. It provides minority groups with a way to understand their culture and their history. It is empowering for the minority, offering them educational opportunities and building their capacity as educated citizens in majority society. If well done, it provides a vehicle for greater intercultural understanding. Finally, it conserves the language resources of a society and builds its capacity for multilingualism (Fishman, 1976).

After contextualizing the traditions and the controversies surrounding minority language education around the world, this article will (1) identify the different power-related dimensions that affect whether a minority language has the possibility of being successfully included in education, and introduce a scale that can be used to predict its ease and success; (2) describe the different ways in which minority language education has been organized, giving examples from different societies.

Traditions, Continuities, Possibilities, and Controversies

Minority language education is not new and it has seldom been uncontroversial. Although common sense would dictate an education in the language of the student, the sociohistorical and socioeducational conditions of states often work against the inclusion of the minority language in state education systems. It is then the tension produced, on the one hand, by the understanding that students should be instructed in their home and community language, and, on the other hand, by the inability or unwillingness of the state to do so, for either political or economic reasons, that surrounds minority language education in controversy.

Minority language education has sometimes been established by educators themselves, many times without official state sanction or funds, and often in private venues. For example, frustrated by the difficulty of evangelizing in Spanish, the language officially sanctioned by the Spanish Empire, missionaries in the New World used the languages of natives during the first two centuries of the Empire. But in 1770, Charles III ordered that only Spanish be used in an effort to spur the spread of Spanish and eradicate the Indian languages (García, 1999). During the Franco dictatorship in 20th-century Spain, *ikastolas*, where Basque children were taught in Euskera (Basque), grew as an underground movement of resistance to schooling in Spanish only (Etxeberria Balerdi, 2001). In the United States, the languages of immigrants, especially German (Standard German), were used in schools throughout the 19th century. But by the early 20th century, and in the wake of the xenophobia surrounding World War I, the practice had become controversial, and 23 states passed laws banning the use of languages other than English in education (Wiley, 1998). Examples of the use of indigenous languages in schooling children in countries in Latin America, beyond those of official bilingual intercultural programs, have been well documented by Hornberger (1997). And throughout the world, language minority groups themselves, especially those with religious affiliations, have organized minority language education programs, sometimes after-school and weekend supplementary programs, other times day schools. This is the case, for example, with the many yeshivas and Islamic schools in New York City, as well as with Mandarin (Mandarin Chinese) after-school and weekend programs.

There are also many examples of officially initiated and supported minority language education programs, although unfortunately many of these efforts continue to meet opposition. In the 20th century, as many African and Asian countries were achieving independence, minority language education was supported, especially by the UNESCO declaration that it is axiomatic to use the child's mother tongue in teaching reading. But the selection of which mother tongue to use as the medium of instruction, and the use of diverse children's mother tongues in the highly multilingual contexts of Africa, has proven problematic (Alidou, 2004; Webb, 2004). Likewise, the transitional bilingual education programs that were created by US federal legislation in the 1970s have recently undergone attack, and by the early 21st century Arizona, California, and Massachusetts had outlawed the practice (Crawford, 2004). The European Union, through the efforts of the European Bureau for Lesser Used Languages and Mercator, supports the development of minority and regional language education, although more attention is often paid to the spread of international languages such as English (Truchot, 2003). It is in contexts where indigenous languages are protected by law and not considered a threat to the majority language that minority language education has gathered momentum and strength. This is the case of Maori-medium education in Aotearoa/New Zealand (May, 2004), of Welsh/Cymru in Wales

(Jones and Martin-Jones, 2004), and of the regional languages of Spain, especially Catalan (Catalan-Valencian-Balear) (Artigal, 1993), since the advent of democracy. When minority language education leads to political and economic advantages, the majority also becomes interested in being included. The exemplar in this case is Quebec, where immersion programs engage the anglophone majority in French-medium instruction (Genesee, 1987).

In the 21st century, as globalization has spurred the movement of people, goods, and services across national boundaries, creating huge linguistic diasporas and the need for communication across languages and in many languages, minority language education has gained in importance, and also in complexity. In societies with high population mobility such as the United States, two-way dual language programs have been developed, involving language minority children with different degrees of proficiency in their heritage or majority language, as well as language majority children. Although problematic (see García, 2004; Valdés, 1997), these programs build on the interculturality of the multiple knowledge bases that shape the transnational/transcultural identities of students in the 21st century.

Power-Related Dimensions of Minority Languages and Their Access to Education

The power-related dimensions identified in Table 1 affect the possibility that minority language education will be developed and successfully implemented with official support. Successful officially sanctioned minority language education depends on the will of the majority, often determined by the linguistic rights it is prepared to cede (Skutnabb-Kangas, 2000), which are related to the historical status of the language (indigenous or immigrant), its economic value, and its uniqueness, that is, whether it is the sole minority language or is in competition with others. But beyond the majority's will lies the will of the minority itself, whether it considers the language important enough to its survival as a people (identity). There are then schooling factors that are important to consider regardless of the will of peoples – whether, as

Table 1 Power-related dimensions for implementation of minority language education

Factors	*Dimension*	*Score = 4*	*Score = 3*	*Score = 2*	*Score = 1*
Majority will factors	Historical power	ML[a] is indigenous language of long standing	ML is indigenous but of more recency	ML is spoken by indigenous settlers and immigrants	ML is spoken only by immigrants
	Economic power	ML has economic value in local and global contexts	ML has economic value only in local context	ML has economic value in other contexts only	ML has no economic value
	Uniqueness power	ML is sole in community and has many speakers	ML has numerical majority, far beyond the other MLs	ML is one of many in community, but is numerically important	ML is one of many in community, and constitutes a small minority
Minority will factors	Identity power	ML and ethnic identity are deeply intertwined	ML is an important ethnic marker to most	ML is an important ethnic marker to some, but not to most	Ethnic identity has lost all link to ML
Schooling factors	Political power	ML has official status in many developed countries	ML has official status in at least one developed country	ML has official status only in developing countries	ML has no official status in any country
	Literacy power	ML has rich literary tradition and academic texts	ML is written but has few published works and few texts	ML lacks written standardization. Academic texts not available.	ML is not written
Organizational factors	Sociolinguistic power	ML is spoken by all or mostly all the ML community	ML is spoken by over $\frac{2}{3}$ of the ML community, both old and young	ML is spoken by approximately $\frac{1}{2}$ of the ML community	ML is spoken by less than $\frac{1}{4}$ of the ML community, mostly aged
	Demographic power	ML community is numerically strong and lives in very isolated communities	ML community is numerically strong and lives in somewhat isolated communities	ML community is demographically weak, although lives in somewhat isolated communities	ML community is demographically weak and lives in integrated communities

[a]ML = minority language.

a result of its official status in other countries (political), there are teachers, books, and a rich literacy and literature tradition (literacy). Finally, the organizational factors of minority language education depend on the sociolinguistic status of the language (whether it has been maintained or has undergone shift) and whether there are many speakers of the same language in isolated schools (demographic).

Table 1 presents a rubric that enables states to determine whether implementation of minority language education would be relatively easy or very difficult. The higher the score, the more likely that minority language education can be implemented successfully and without too much effort. It is important to point out, however, that despite low scores, some language minority communities succeed on their own, and without external support, in running highly successful minority language education efforts.

Organization of Minority Language Education around the World

Although, as stated above, minority language education is not new, it was in the 20th century, and specifically after the UNESCO declaration of 1953 supporting the teaching of reading in the children's mother tongue, that it was first considered a field of study. The organization of minority language education responds to the different sociolinguistic and sociopolitical needs of different societies and language communities. At least seven different organizational models of minority language education coexist in the world today, and examples of such models in different societies follow.

1. *Heritage language education models*, specifically supplementary (after-school and weekend) classes, are often run by the minority language community itself to maintain and develop the heritage language in the language minority community. Instruction is most often solely in the minority language. Programs of this type are found throughout the world.

2. *Developmental maintenance bilingual education (DMBE) models* are either private all-day schools organized and run by the language minority community itself or state-funded all-day schools. Instruction is in two languages, with some portion of the school curriculum or day taught in the majority language and the other taught in the minority language.

Sometimes, the more ethnically encumbered subjects (such as history and social studies) are taught in the minority language, and the other subjects are taught in the majority language. This is the case, for example, with the Hebrew day schools in the United States, which use Biblical Hebrew for the study of the Old Testament and the Commentaries, modern Hebrew to teach the history of Israel, and English to teach all secular subjects. This is also the case of schools in the Philippines, which reserve Filipino (Tagalog) to teach Philippine history and literature and use English to teach math and science (Gonzalez, 1998).

The strict compartmentalization and functional complementary of languages observed in the DMBE model of the Philippines contrasts sharply with that in Wales. The purpose of the DMBE model in the Philippines was to spread Filipino (Tagalog) as a national language in a highly multilingual context, and thus it was formally protected. In Wales, however, Welsh and English are used to teach all subjects, with a great deal of instructional code-switching used to contextualize Welsh for those for whom it is not a mother tongue, as well as for those who have undergone language shift (Jones and Martin-Jones, 2004).

DMBE models do not always devote equal time to the two languages. Sometimes, as in the Cuban-American schools in Dade County, Florida (García and Otheguy, 1988), Greek day schools throughout the world, or the Frisian (Western Frisian) schools in Friesland (Zondag, 1988), the minority language is used as a medium of instruction only for literacy-related functions, and often for just one instructional period a day. Usually, the minority language is taught by a different teacher.

3. *Heritage immersion bilingual education models* have been developed in societal contexts where there has been a high degree of language shift. In an effort to reverse the language shift that had occurred in Aotearoa/New Zealand, the Kóhanga Reo movement established nursery schools completely run in Maori by the community elders. Those early immersion efforts have now been complemented by the establishment of *kura kaupapa* bilingual schools, following a developmental maintenance model (May, 2004). Likewise, immersion bilingual education models where language minority children are initially immersed in their heritage language are now prevalent in Scotland for Gaelic (Scots Gaelic), Ireland for Irish (Irish Gaelic), and Spain for Euskera (Basque), societies in which there has been a great deal of language shift. Immersion in the minority language is always followed by an education which balances the minority with the majority language.

4. *Bilingual intercultural education models* are prevalent in Latin America for indigenous groups who have traditionally received a poor Spanish-medium education. Bilingual intercultural education is available in Aymara, Guarani (Guaraní) and especially Quechua/Quichua, among others, alongside Spanish. The purpose of such minority language education is to provide basic literacy to the

indigenous population, while giving them the intercultural skills that enable them to interact in the Spanish-speaking world (López, 1995). Despite legislation supporting intercultural bilingual education, programs are few and often experimental in nature.

5. *Transitional bilingual education models* exist mostly in contexts with a high degree of immigration such as the United States, or in countries of Africa and Asia where minority language education lasts only until the child acquires the majority language. Transitional bilingual education models are an example of subtractive minority language education and lead away from the minority language to the majority language.

6. *Two-way bilingual education models* provide language minority children with an education in their heritage language, while making it possible for language majority children to learn the minority language. Although these models usually keep the two linguistic groups separate during the period of emerging bilingualism, especially for literacy instruction, the recent programs developed in the United States insist on the linguistic integration of children at all times. This linguistic integration often works better for the acquisition of English than for the maintenance and development of the minority language (García, 2004).

7. *Language Awareness and Inclusive models* are organized in contexts where the minority language speakers are integrated throughout the school system and it is impossible to provide them with minority language education. It cannot be considered minority language education in its own right. Children in these models are encouraged to use the minority languages to read, find information, and write reports (García, 2000). Language awareness models specifically encourage children to compare and contrast their minority language to the majority one (James and Garrett, 1991). The teacher does not instruct in the minority language or about the minority language since she or he rarely has knowledge of the minority language.

Conclusion

Minority language education is very important, but it is fraught with controversy and challenges. By using the scale provided here, educators will be able to determine the kinds of human and financial resources needed to implement minority language education successfully. Each society and community will have to determine the kinds of models that it can support. More minority language education is better than less, and its absence in a society is a sure sign that a large proportion of the school-age population is being excluded from a meaningful education.

Minority Languages: Oppression

S Baines, Universidade de Brasília, Brasília, Brazil

Throughout history, minority languages have been very frequently subjected to oppression and often extinction by state policies rooted in colonial and neocolonial traditions, which aim at linguistic and cultural homogeneity, and also by majority ethnic groups within national states in their efforts to culturally and linguistically dominate and oppress minority groups. In addition, many minority indigenous groups, together with their cultures and languages, have been completely wiped out by introduced epidemics. As part of ethnocentric 'civilizing' projects, which see indigenous languages and cultures as inferior and discriminate against native speakers for using their own languages, the work of traditional missionaries, until recent decades, has also frequently prohibited the use of indigenous languages. In 1981, the Tukano leader Álvaro Sampaio denounced at the Russell Tribunal in Holland that, in the Upper Rio Negro region of Amazonas, Brazil, many indigenous languages disappeared as a result of (mission) boarding schools, where the use of Portuguese was enforced and the use of indigenous languages was prohibited (Sampaio, 1981: 13). Some indigenous peoples, especially in urban settings, facing violent discrimination and, having become ashamed to speak their own languages, avoid teaching their children their language out of fear that they too will be discriminated and, thereby, have fewer chances of a better life.

Historical evidence shows that, when prestige has been conferred on a minority language, it has more chances of survival. The valuing of the Navajo language as a code language by the U.S. government in World War II led to an increase in its use at the time. James Crawford (1998), referring to endangered native languages in North America, outlined the acute loss of these languages; even in the case of languages which have large populations of speakers such as Navajo (148 530 in 1990, which accounts for 45% of all native American language speakers in the U.S.), the percentage of Navajo who speak only English is increasing. Crawford presented Census Bureau data to show that between 1980 and 1990, among school-age Navajo children living on the reservation, the number of monolingual English speakers more than doubled. Crawford stressed the need to examine the social and historical causes of 'language loss' and the failure on the part of many linguists, in an attempt to separate external and internal factors, to take proper account of the question. This author further demonstrated how the coercive assimilation policy, as practiced by the Bureau of Indian Affairs from the late 1880s until recent decades, has alienated many native people from their cultural roots. In contrast, from the 1980s several indigenous peoples have adopted policies which aim at promoting the use of their languages. Citing Krauss (1992), Crawford emphasized that the will to revive or maintain native languages must come from the speakers, who must feel a need to value their languages (*see* **Pragmatics: Linguistic Imperialism; Linguistic Decolonization**).

Minority Languages: Oppression

S Baines, Universidade de Brasília, Brasília, Brazil

Throughout history, minority languages have been very frequently subjected to oppression and often extinction by state policies rooted in colonial and neocolonial traditions, which aim at linguistic and cultural homogeneity, and also by majority ethnic groups within national states in their efforts to culturally and linguistically dominate and oppress minority groups. In addition, many minority indigenous groups, together with their cultures and languages, have been completely wiped out by introduced epidemics. As part of ethnocentric 'civilizing' projects, which see indigenous languages and cultures as inferior and discriminate against native speakers for using their own languages, the work of traditional missionaries, until recent decades, has also frequently prohibited the use of indigenous languages. In 1981, the Tukano leader Álvaro Sampaio denounced at the Russell Tribunal in Holland that, in the Upper Rio Negro region of Amazonas, Brazil, many indigenous languages disappeared as a result of (mission) boarding schools, where the use of Portuguese was enforced and the use of indigenous languages was prohibited (Sampaio, 1981: 13). Some indigenous peoples, especially in urban settings, facing violent discrimination and, having become ashamed to speak their own languages, avoid teaching their children their language out of fear that they too will be discriminated and, thereby, have fewer chances of a better life.

Historical evidence shows that, when prestige has been conferred on a minority language, it has more chances of survival. The valuing of the Navajo language as a code language by the U.S. government in World War II led to an increase in its use at the time. James Crawford (1998), referring to endangered native languages in North America, outlined the acute loss of these languages; even in the case of languages which have large populations of speakers such as Navajo (148 530 in 1990, which accounts for 45% of all native American language speakers in the U.S.), the percentage of Navajo who speak only English is increasing. Crawford presented Census Bureau data to show that between 1980 and 1990, among school-age Navajo children living on the reservation, the number of monolingual English speakers more than doubled. Crawford stressed the need to examine the social and historical causes of 'language loss' and the failure on the part of many linguists, in an attempt to separate external and internal factors, to take proper account of the question. This author further demonstrated how the coercive assimilation policy, as practiced by the Bureau of Indian Affairs from the late 1880s until recent decades, has alienated many native people from their cultural roots. In contrast, from the 1980s several indigenous peoples have adopted policies which aim at promoting the use of their languages. Citing Krauss (1992), Crawford emphasized that the will to revive or maintain native languages must come from the speakers, who must feel a need to value their languages (*see* **Pragmatics: Linguistic Imperialism; Linguistic Decolonization**).

After a long history of oppression, there have been some recent governmental initiatives such as the Native American Language Acts of 1990 and 1992 in the United States, aiming to promote the protection of indigenous languages with a grant program. A Universal Declaration of Linguistic Rights was drawn up at a meeting of institutions and nongovernment organizations that took place in Barcelona, Spain, in June 1996. It was asserted that invasion, colonization, occupation, and other instances of political, economic, or social subordination often involve the direct imposition of a foreign language, distorting the perception of the value of 'native' languages. This was the first time that the claim to be able to exercise freedom of speech in the language of one's choosing was clearly stated. Some years later, at the 31st session of the UNESCO General Conference in Paris (November 2, 2001), the UNESCO Universal Declaration on Cultural Diversity was adopted as a legal statement that recognizes, for the first time, cultural diversity as a 'common heritage of humanity' and considers its safeguarding to be a concrete and ethical imperative, inseparable from the respect for human dignity. In 2001, the UNESCO published an atlas of endangered languages (Wurm, 2001) (*see* **Linguistic Rights**).

Crawford (1998) argued that, in defending the protection of minority languages, the most effective line of argument is an appeal to social justice. The loss of culture and language can, he stressed, destroy a sense of self-worth. Language death occurs to the dispossessed and the disempowered peoples who most need their cultural resources to survive under hegemonic pressures. The oppression of minority languages must be seen as part of a much more encompassing cultural and political oppression, in which any divergent political discourse is oppressed. Jacob Mey argued that an alternative strategy to brutal political repression by hegemonic powers is that "the hegemonic forces of the political majority may take their aim at disrupting the minority's possibilities of participating in the ongoing political discourse by eliminating the access for minority cultures to the exercise of their free speech rights in their own tongues" (1994: 154). The developing field of pragmatics (Mey, 2001) – the study of language from the perspective of its users, of the choices they make, the constraints they encounter in the use of language in social interaction, and the effects their use of language has on other participants in communication – provides an important tool for studying the oppression of minority languages. This and similar approaches stress the socially oriented thinking that sees language primarily as a means of communication between human users (*see* **Pragmatics: Overview**; **Social Aspects of Pragmatics**).

One of the pioneers in showing a concern about the oppression of minority languages is the anthropologist-linguist Edward Sapir (1884–1939) (*see* **Sapir, Edward (1884–1939)**), trained by Franz Boas in the early 20th century. Being the only professionally trained linguist among Boas's students, Sapir showed a concern for the need to record endangered Amerindian languages before they were lost to humanity. In 1915, on the Berkeley anthropologist Alfred L. Kroeber's invitation, Sapir went to work in California with Ishi, the last speaker of Yahi, a Yana language, recording the language and culture (1917) (*see* **Anthropology and Pragmatics**).

Jay Powell of the University of British Columbia and Michael Krauss of the Alaska Native Language Center of the University of Alaska have carried out important research on language loss and participated in attempts to revitalize languages which have been oppressed, with varying degrees of success. Powell defended the symbolic significance of revitalizing indigenous languages; even when the language does not become fluently spoken again, the use of indigenous words or phrases can help give value and meaning to indigenous cultures and strengthen a sense of indigenous cultural identity. The philosopher Marcelo Dascal (2004) drew attention to the cognitive, emotive, cultural, social, and political functions of languages that, in addition to being tools of communication, carry traditions and cultures.

Among recent works, David Crystal (2000) examined the threat to minority languages and revealed a concern to retain the linguistic and cultural diversity in the world, estimated to comprise 6000 languages in the year 2000. Crystal defined language death, presenting reasons for his concern for the alarming rate of loss of languages (one language dying every two weeks) (2000: 19). He calculated that 4% of the world's 6 billion inhabitants speak 96% of the languages (2000: 14); for 51 languages a lone speaker survived, while 25% of languages had less than 1000 speakers. Crystal explored contributing factors, a major one being negative attitudes to a language, in government policy and local communities. He presented considerations as to how to redress the situation. From his argument of the value of languages, Crystal showed that the attribution of prestige to a threatened language and policies to promote the empowerment of its speakers, given better economic conditions, are favorable factors for its survival.

R. M. W. Dixon (1980) estimated in 1980 that in Australia around 25% of the original languages were extinct and 50% threatened with extinction. Anette Schmidt (1990), ten years later, estimated that 64% are extinct or have only a few elderly speakers, and that 28% are severely threatened. Of the 90 languages

this author described as 'surviving,' 70 are classified as being threatened or severely endangered.

Andrew Dalby (2003) focused especially on the linguistic history of Europe and the processes by which minority languages are lost. Lenore Grenoble and Lindsay Whaley (1998) offered an overview of the issues involved in language loss, combining articles of authors of different backgrounds to provide sociological and economic as well as linguistic perspectives on language loss. After an overview of language endangerment, their book presents the situation confronting threatened languages, the issue of what can be lost as a language ceases to be spoken, and the linguistic processes involved.

Daniel Nettle and Suzanne Romaine (2000) related ecological and linguistic vitality, and examined assumptions about why languages die and how some languages have become dominant; however, their approach has a predominantly ecological bias. Tove Skutnabb-Kangas (2000) examined how most indigenous and minority education contributes to linguistic genocide from a multidisciplinary perspective. This author combined different theoretical concerns such as linguistic human rights, minority and multilingual education, language ecology and threatened languages, the impact of linguistic imperialism and unequal power relations on ethnicity, linguistic and cultural competence, and identities. The book presents many empirical examples from around the globe.

Darcy Ribeiro estimated that between 1900 and 1957, 87 indigenous peoples with their languages and cultures had become extinct in Brazil (1979: 239). Aryon Rodrigues (1993) affirmed that there were about 1273 indigenous languages spoken in Brazil in 1500; here, the loss is of the order of 85% (1993). Bruna Franchetto estimated that, of the 180 languages spoken today in Brazil, the average number of speakers per language is less than 200 (2000: 84–88).

After centuries of oppression, with the rise of indigenous political movements, especially since the 1970s, there have been attempts to demand respect for cultural and linguistic plurality. Efforts have been made to revitalize languages seen as being on the way to extinction, and to revive languages that have become extinct. In the past two decades, constitutional amendments have been introduced in many national states that aim to recognize cultural and linguistic plurality parallel to movements of ethnic and linguistic resurgence. However, despite the very rapid growth of indigenous and minority ethnic group cultural and political movements, the revitalization of oppressed languages occurs in radically different ways across the globe. Rita Segato (1999: 162) observed that some voices, which celebrate the process of 'globalization' and do not interpret it as an exacerbation of imperialism, subscribe to the idea that only as a consequence of the internationalization of modern ideas about citizenship and human rights has it become possible for previously invisible peoples to emerge and today claim rights in the name of their identity. Segato proposed that this is only partly true, and pointed to the fact that we are dealing with an ambiguous and unstable process, capable on the one hand of affirming minorities' rights, but, on the other hand, homogenizing cultures, flattening their lexicons and values, so that they can enter the generalized dispute for resources (1999: 162–163).

In examining the oppression of minority languages and cultures, a dynamic concept of culture is necessary. Language and culture are dynamic and in constant change, embodying a set of meanings – beliefs, values, knowledge – in an ongoing process of construction, reconstruction, and transformation. Traditions are revitalized, reinvented, and lived through languages. However, many minority languages and cultures suffer violent oppression not only from strictly language-oriented policies (such as practiced in education), but also by the encroachment of national societies on the lands of indigenous peoples and as part of cultural and political domination.

The History of Linguistics and the Linguistic Work of Missionaries

Most of the languages spoken today – estimates range from 3000 to 6000 – never gained any official status, most are not written, they are not taught in school and there is nothing like a dictionary, a grammar or even a primer. Yet a considerable number of descriptions of such languages do, in fact, exist. Most of them were, and still are, composed by missionaries. From the very beginning of European expansion to other continents, missionaries set out to convert the uncivilized and the pagan peoples. Languages of the Americas, Australia and Africa, of Southeast Asia and Polynesia, were affected most by the efforts of missionaries of various denominations. It is well known that most of the indigenous languages of North America and Australia today are at the verge of extinction or are already extinct. Sometimes their documentation by missionaries is the only one bearing testimony, providing today's scholars with invaluable information that otherwise would no longer be available. In those cases where the languages are still spoken, such knowledge helps to establish a diachronic dimension, however shallow it may be.

Although the existence of such grammars, dictionaries or notebooks was well known and sometimes even extended bibliographies were compiled, such as Pilling's (Pilling, 1973), hardly any research was done on this considerable body of material, with the notable exception of Victor Hanzeli's *Missionary linguistics in New France*, written in 1969 (Hanzeli, 1969). Even when the interest in the history of linguistics set in, in the 1970s, it did not extend to descriptive works on exotic languages. The very obvious shortcomings of many of the missionaries' linguistic efforts, their being shaped by the formulae of Latin-based grammar, and the way such work came about did not help to stir much interest. At the same time, the rise of syntactic theory and its claims as to general validity, the simultaneous spread of language typology, its pronounced interest in linguistic diversity and its corpus-based methodology, caused a new interest in languages other than the well-known Indo-European ones and finally gave rise to first attempts at grammars on structurally interesting, i.e., deviating, languages

The History of Linguistics and the Linguistic Work of Missionaries

Most of the languages spoken today – estimates range from 3000 to 6000 – never gained any official status, most are not written, they are not taught in school and there is nothing like a dictionary, a grammar or even a primer. Yet a considerable number of descriptions of such languages do, in fact, exist. Most of them were, and still are, composed by missionaries. From the very beginning of European expansion to other continents, missionaries set out to convert the uncivilized and the pagan peoples. Languages of the Americas, Australia and Africa, of Southeast Asia and Polynesia, were affected most by the efforts of missionaries of various denominations. It is well known that most of the indigenous languages of North America and Australia today are at the verge of extinction or are already extinct. Sometimes their documentation by missionaries is the only one bearing testimony, providing today's scholars with invaluable information that otherwise would no longer be available. In those cases where the languages are still spoken, such knowledge helps to establish a diachronic dimension, however shallow it may be.

Although the existence of such grammars, dictionaries or notebooks was well known and sometimes even extended bibliographies were compiled, such as Pilling's (Pilling, 1973), hardly any research was done on this considerable body of material, with the notable exception of Victor Hanzeli's *Missionary linguistics in New France*, written in 1969 (Hanzeli, 1969). Even when the interest in the history of linguistics set in, in the 1970s, it did not extend to descriptive works on exotic languages. The very obvious shortcomings of many of the missionaries' linguistic efforts, their being shaped by the formulae of Latin-based grammar, and the way such work came about did not help to stir much interest. At the same time, the rise of syntactic theory and its claims as to general validity, the simultaneous spread of language typology, its pronounced interest in linguistic diversity and its corpus-based methodology, caused a new interest in languages other than the well-known Indo-European ones and finally gave rise to first attempts at grammars on structurally interesting, i.e., deviating, languages

under theoretical and methodological perspectives. Until the late 19th century, grammars and descriptions of such languages were not composed by linguists or philologists. In most cases they were compiled in the course of Christianization by missionaries living in the respective area. Having today's knowledge and perspectives in mind, the critical consultation of these first representations may help to reconstruct the genesis of prevailing opinions on grammatical structures, especially unfamiliar ones such as ergativity, syntactic nonconfigurationality, or polysynthesis. Yet today only two or three articles and a few collections of papers are dedicated to such investigations, some also including reflections on linguistics methodology, especially the overall role of empirical research in the history of linguistics. It must also be noted that even today many linguists doing field work are related to a missionary society or church, such as the *Summer Institute of Linguistics*. Critical reviews of earlier work of missionaries are not necessarily welcome and it is rather their labors and good intentions that are appreciated. Attempts at reconstructing the influence of occasional mother tongue knowledge of the author on the development of grammatical representations, or their modification, as is the case with Samuel Kleinschmidt's grammar of 1851 (Kleinschmidt, 1851), are of great value but rather rare. They require an in-depth knowledge of the respective language by the historiographer.

Missionaries as Linguists

From the beginning of European colonial expansion, Christianization and the establishment of trade were seen as being important for gaining political influence and subsequently power. In the early period, the need to communicate with the local population was especially pronounced with respect to conversion to Christianity, which in turn was seen as a step towards 'civilizing,' i.e., pacifying the local populations. Missionaries as men of the word seemed predestined to tackle the foreign tongues. Subsequently, most, if not all grammars of exotic languages from the 16th century onwards, were composed by missionaries. The Catholic church and her missionaries of various orders exerted enormous influence in Central and South America, and parts of North America. Missionaries of Protestant churches, such as the Anglican Church, and numerous evangelical congregations became active in the British sphere of influence. Spheres of political power are largely mirrored by the spheres of missionary activities and the impact they made on the local population.

It must be emphasized that initially, languages were not described out of scientific interest, but because of very practical needs for communication. The descriptions share a number of characteristic features, yet at the same time each piece is unmistakably shaped by very specific factors, the most important being the capability of the author. To master the language was a necessary exercise the missionaries had to undergo – for most missionaries, a tiring and demanding experience. Most of them were not exactly ambitious with respect to the composition of a grammar, and many were not capable of achieving more than the most elementary outline. The educational background of the missionaries influenced their linguistic work greatly. The different standards of training between the clergy and the members of evangelical congregations, who most often were lay people with little if any formal education, are all too obvious. As a rule, descriptions and manuals were composed exclusively for the use by fellow missionaries. Genuine interest in the language itself developed with some individuals, as did the urge to improve and adjust the template provided by the standard Latinate grammar. This is especially true of later generations of missionary linguists, when, in some cases, mother tongue speakers could add their knowledge to the description of the respective language.

Impact on the Languages

Most grammars were not published, but merely circulated as manuscripts within the mission, copied and developed further, but they were hardly ever fundamentally revised. Within the orders or congregations, they were of considerable influence and by being frequently in use over long periods of time standards were established.

The translation of the bible was of utmost importance to all Protestant missions, and many evangelical congregations would only accept converts who had proven their understanding of the bible. Bible translation required not only a very good command of the language and the coining of a new terminology, but also the representation of the speech sounds by letters. The attempts at teaching how to read the Bible initiated the introduction of schooling for the native population. The establishment of a writing standard, of whatever quality, in most cases greatly influenced the respective language. Besides the bible, other books were printed and circulated, and in many cases writing was taken up for everyday life and gained importance beyond religious matters. Literacy became part of the respective culture. Yet in other cases, most prominently in the Catholic sphere of influence, reading was not propagated and writing never reached the population, which sometimes remains largely illiterate until today. In yet other

cases, competition between missions led to an unnatural diversification of otherwise closely related languages – or even the same language. The impact on the target languages varies to a large extent, but still missionaries were teachers, and education, especially with respect to the teaching of reading and writing, is of utmost importance for a speech community. While in time revisions and improvements were made, and education was subsequently handed over to other institutions, in some cases this never happened. The missionaries' standards became part of the cultural identity and tradition and, as heritage, today are fiercely defended, no matter how useful and appropriate a revision might be.

Reception in the Scholarly World

As for the scholarly public, or the interested public, grammars and descriptions composed by missionaries were not readily accessible, since most were not published. But motivated by the debates of enlightenment, scholars tried to get hold of as much information as possible, usually through correspondence or personal relations. Humboldt's treatises on the Mexican grammar (Humboldt, 1996), for example, are based on such manuscripts, his judgment on their qualities, however, is rather harsh and unfavorable. The ingenious grammar written by a missionary is by far the exception, not the rule. Whether an influence of the linguistic achievements of missionaries on the prevailing standards of grammar writing of the time can be traced, seems to be rather dubious. Even in those cases where attempts at grasping the peculiarities of these alien tongues were made, they were more often than not dismissed or doubted by the scholarly public. The concept of cultural and intellectual superiority, mirrored by the structure of the languages, was so deeply rooted that even Humboldt could not accept the fact that the inflectional system of Nahuatl, the Mexican language, is richer than that of Ancient Greek. His controversy with John Pickering concerning the nature of polysynthesis illustrates the intellectual bias prevailing at his time – and a long time to come. To give one more example, Kleinschmidt's grammar (Kleinschmidt, 1851), published in Berlin and earning him an honorary doctorate, was consistently ignored by European scholars, underestimated or criticized, and its potential contribution to the debates on ergativity or polysynthesis was not recognized.

Considering how slowly peculiarities of European vernaculars made their way in to grammatical terminology, it seems even more unlikely that those of indigenous languages should have been more successful.

In the second half of the 19th century, when in North America ethnographic and linguistic interest in the vanishing indigenous cultures and peoples instigated a rush to taking record of the languages still existing, geologists and others surveying the land were equipped with explicit instructions for the elicitation of language data. By the end of the 19th century, in North America fieldwork had become an institutionalized part of the emerging sciences of anthropology and linguistics. Yet today's role of missionary societies should not be underestimated. They are still most active in the field and so are exquisitely trained missionaries who are linguists.

Misumalpan

A Constenla Umaña, University of Costa Rica, San José, Costa Rica

© 2006 Elsevier Ltd. All rights reserved.. All rights reserved.

Misumalpan is a Central American linguistic family with five members: Cacaopera, Matagalpa, Miskito, Sumo (Sumo Tawahka), and Ulwa. Cacaopera was spoken in eastern El Salvador and became extinct during the first half of the 20th century. Matagalpa, once diffused through the western portions of mid- and northern Nicaragua, and in the immediate adjacent zone of southern Honduras, became extinct at the end of the 19th century. Sumo is the language of 9000 people in northeastern Nicaragua (the area of the Waspuk and Bambana rivers) and about 500 people in the neighboring area of Honduras (along the middle Patuca River). Sumo has two dialects: Panamahka, which includes 80% of the speakers, and Tawahka. Ulwa, formerly widespread in southeastern Nicaragua, is currently spoken by about 500 people in the area of the lower Grande de Matagalpa and Kuringwas rivers. Miskito is spoken in the Caribbean coast and neighboring lowlands from the Black River in Honduras (25 000 speakers) to the Pearl Lagoon in Nicaragua (100 000 speakers). The following dialects are mentioned: Mam (Honduras), Wangki, Tawira, Baldam, and Kabo (Nicaragua).

Ulwa and Sumo on the one hand, and Matagalpa and Cacaopera on the other, constitute two uncontroversial subgroups. Lexicostatistics show a closer relationship between them than that of either one to Miskito, so the family seems to be basically divided into the latter and what we could call Western Misumalpan. The time depths according to glottochronology are Miskito/Western Misumalpan, 5800; Sumo–Ulwa/Matagalpa–Cacaopera, 5300; Matagalpa/Cacaopera, 1200; and Sumo/Ulwa, 880.

The only external relationship that has been proven by means of the comparative method is that with the Lencan family from Honduras and El Salvador. The split of the common ancestor would have taken place about 7200 years ago.

Many have thought Misumalpan to be related to Chibchan. This seems probable but has not yet been properly demonstrated.

The Misumalpan languages belong to the Lower Central America linguistic area, characterized by features such as SOV order, postpositions, preposed genitive, postposed numerals and adjectives, and contrasts between voiced and voiceless stops. Inside the area, they are part of a Northern Subarea characterized by features such as person inflection for possession in nouns and for agent and patient in verbs, predominance of accusative-nominative case systems, serial verb constructions, postposed or suffixed negation, and vowel length contrasts.

Mitigation

C Caffi, Genoa University, Genoa, Italy

© 2006 Elsevier Ltd. All rights reserved.

In everyday language, 'mitigation' as an action noun can refer both to the action of mitigating, and to the fact of being mitigated. The former sense foregrounds the process, the latter the result. In the technical use of the term, mitigation is an all-embracing category employed in pragmatics (*see* **Pragmatics: Overview**) to label the wide set of strategies by which speakers attenuate one or more aspects of their speech.

Many rhetorical figures, such as periphrasis, euphemism, litotes, understatement, meiosis, or reticence, can be subsumed under the label 'mitigation,' as they can all be viewed as saying less, while not necessarily meaning more. In mitigation, something which is somehow expected, is substituted, side-stepped, disguised, or simply deleted and left unsaid by the speaker, out of manners, cautiousness, or modesty: it is up to the hearer to reconstruct it inferentially.

The notion and the term were introduced in pragmatics by Fraser (1980) to refer to the linguistic devices by which speakers try to protect themselves against various kind of interactional risks. Fraser (1980) listed the following as typical mitigating devices in English: indirect acts and justification moves (especially for directives), passive and impersonal constructions where references to speaker and hearer are deleted, epistemic disclaimers (e.g., *If I'm not wrong*) and non-epistemic disclaimers (e.g., *I hate to do this, but…*, *If you wouldn't mind…*), parenthetical forms and modal adverbs reducing commitment to the proposition (e.g., *probably*, *possibly*, etc.), tag questions, hedges (e.g., *technically*) in Lakoff's (1973) sense of the term. According to Fraser (1980), mitigation can be 'self-serving,' in which case it aims at avoiding possible unwelcome outcomes for the speaker, or 'altruistic,' in which case it aims at reducing negative effects for the hearer.

Historical Background

Both the term (*mitigatio*) and the notion itself are found in the *Rhetorica ad Herennium*, a treatise from the second decade of the 1st century B.C., of uncertain authorship, usually attributed to Cicero. This manual transposes the Greek art of rhetoric (*see* **Rhetoric, Classical**) into the practical Roman spirit; the author describes the effect of *deminutio* ('belittlement') and explains that it should be used, out of prudence, to avoid antagonism and antipathy in speaking (*Rhet. Her.*, IV, XXXVII, 50).

Mitigation has been used as a technical notion in linguistic pragmatics since the late 1970s, when a main concern in pragmatic research was to make the concept of illocutionary act (Austin, 1962) operational in the analysis of discourse.

From this period on, in the vast research field on politeness (a vastness that is well documented, among others, by Kasper, 1990; Watts *et al.*, 1992; DuFon *et al.*, 1994), some mitigation-related notions, if not the term, are overtly or covertly at work. Among these, the most influential model of politeness (*see* **Politeness**), that of Brown and Levinson (1987 [1978]), treats mitigation as a synonym of politeness (1987: 42). The 'face-saving view' of interaction (Fraser, 1990), based on Goffman's notion of 'face' (Goffman, 1967; for a reexamination, see the Focus-on Issue on 'Face' of the *Journal of Pragmatics,* 2003) (*see* **Goffman, Erving (1922–1982); Face**), has the idea of mitigation at its core: the strategies of both positive politeness (related to social approval) and of negative politeness (related to privacy and autonomy) can be read as mitigating strategies. Subsequent research into politeness, which is more directly linked to mitigation, has focused on the devices that minimize the impact of a face-threatening act (FTA), especially requests. The 'maxims of politeness' put forward by Leech (1983: 132ff) in his model of discourse, in particular the 'Tact Maxim,' all have a bearing on mitigation as they are based on a general 'interpersonal rhetoric,' which mainly aims at avoiding disagreement and at fostering agreement between interlocutors (*see* **Maxims and Flouting**).

Significantly, the notion of mitigation becomes a widely recognized analytical tool when the epistemological orientation in pragmatics shifts from an introspective, philosophically oriented paradigm to an empirical one that is increasingly addressing real, non-constructed data, in *situated* contexts (in the sense assigned to the term by Mey, 2001: 219ff).

These two requirements (non-constructed data that are taken from, or are characteristic of, specific interactional contexts) are distinctive features of studies in which mitigation is used. In particular, Labov and

Fanshel (1977), in their thorough analysis of one session of therapy between Rhoda, a girl suffering from anorexia, and her psychotherapist, introduce the concept of mitigation as opposed to that of 'aggravation' to designate two "basic interactive dimensions" (p. 84). Mitigation is rooted in "the subject's desire to mitigate or modify his [*sic*] expression to avoid creating offense" (1977: 84). In a pedagogical framework, Edmondson and House (1989), applying Edmondson's (1981) theoretical model, propose many moves that are conceptually related to mitigation inasmuch as they can be described as 'hearer-supportive.' Specifically, Edmondson (1981: 115ff) proposes three types of supportive moves, viz. grounders, expanders, and disarmers, which play mitigating functions. In a similar vein, Meyer-Hermann and Weingarten (1982) focus on psychotherapeutic conversation, whereas Langner (1994) takes his data from college classroom interaction. Both these works use an interesting notion of mitigation (German: *Abschwächung*) which is defined as a reduction of obligations for the interlocutors. Prince *et al.* (1982), based on a corpus of physician-physician dialogues, is a study of the linguistic means doctors use in order to be cautious and to weigh the degree of certainty of their utterances. Two main types of modifications are distinguished: 'approximators' (roughly corresponding to Lakoff's [1973] 'hedges') and 'shields,' i.e., expressions "conveying some markedness with respect to speaker's commitment" (Prince *et al.*, 1982: 86).

Among the works that do not only apply the concept but propose insights on its grounding and functioning, Holmes (1984) concentrates on strategies that attenuate or reinforce ('boost') illocutionary force. Moving on from Fraser (1980), Holmes (1984) treats mitigation as a particular case of attenuation, occurring when the predictable effects of a speech act (*see* **Speech Acts**) are negative. According to Holmes, attenuation devices affecting illocutionary force can be grouped into the following four categories: (1) prosodic devices (e.g., a falling-rising intonational contour, realizing the epistemic mode in English, decreased emphasis, lower voice, etc.); (2) syntactic devices (e.g., tag questions, impersonal constructions, double negatives in formal discourse, etc.); (3) lexical devices; and (4) discourse devices (e.g., digression indicators like *by the way*, which, as already observed by Brown and Levinson [1978: 174], reduce the relevance of the utterance they introduce). Lexical devices are further divided into: attenuating devices focusing on the speaker (for instance, parenthetical expressions such as *I gather*, *I guess*, *I suppose*); attenuating devices focusing on the hearer (e.g., *you know*, *if you don't mind*, *if you are sure that's OK*); and attenuating devices focusing on content or 'other.' This latter category includes attenuating mechanisms realized by epistemic adverbials such as *possibly* and *probably*, and adverbials displacing the responsibility for what is being said to other sources (e.g., *allegedly, reportedly, presumably*).

Blum-Kulka *et al.*'s (1989) study in the framework of a research project on cross-cultural speech act realization (CCSARP) is centered on the linguistic realizations of requests and apologies in various languages, with different degrees of conventionalization. As to requests, these lend themselves to mitigation more easily than do other speech acts because they are inherently invasive of the other's territory, being face-threatening acts (FTA) in Brown and Levinson's (1987 [1978]) terms (*see* **Face**). Conversely, apologies tend to be reinforced in order to be more effective. The authors draw a distinction between internal and external mitigation: the former occurs within the speech act, while the latter occurs outside it and corresponds to what in other frameworks (*see* **Conversation Analysis**) are called 'pre-sequences' or 'grounders.' As documented by Blum-Kulka *et al.*'s important collection of data, the category 'mitigation' proves to be useful for the interethnic comparison of different strategies of performance of speech acts in cross-cultural research (*see* **Intercultural Pragmatics and Communication**).

Theoretical Questions

Even from the brief overview above, it appears that diverse notions of mitigation, in different approaches and in varying terminology (from 'cajolers' to 'sweeteners,' from 'softeners' to 'disarmers,' from 'rounders' to 'shields,' etc.), all rely on some assumptions that can be summarized in the following points:

1. the notion of mitigation presupposes that an illocutionary act can be modified; in other words, illocutionary force can be seen as having degrees of strength (among others, Holmes, 1984; Sbisà, 2001);
2. such a modification calls into play an intensity factor that in many cases can be thought of as scalar;
3. the intensity factor itself can be modified in the direction of a weakening (resulting in what is called 'mitigation,' 'attenuation,' 'downgrading,' etc.) or in the direction of a strengthening (resulting in what is called 'reinforcement,' 'upgrading,' 'boosting,' etc.). Caffi (1990) proposes the superordinate category 'modulation' to refer to both directions of modification.

In the case of weakening, in particular mitigation, some questions arise; these may be grouped in three

sets. The first set is relevant from a descriptive viewpoint and can be formulated as follows:

> i. Leaving aside the important role played in mitigation by nonverbal means (in particular, proxemic and kinesic cues, such as smiles, gestures, postures, etc.), what are the kinds of mitigating devices that a natural language offers as resources for situated interaction? Are they mainly lexical, morphological, syntactic, or prosodic? Which combinations of different devices are more often attested in use? Is it possible to map types of mitigating strategies onto types of interaction? Is it possible to discover significant distributional constraints on mitigating devices and strategies used for performing different (macro-)types of illocutionary acts?

The second set of questions, at a higher level of abstraction, can be summed up as follows:

> ii. What is it that is weakened by mitigators? In other words, what is the linguistic scope, whether lexicalized or not, that is affected by the mitigating operation? Is there a correlation between the abstract scope of the linguistic mitigating device and the inferrable effect with respect to the value assigned to a given interactional dimension? What modifications are a matter of degree and what a matter of type? How do different kinds of mitigating devices interact? With which results? It should be noted that these questions are not abstractly speculative but have a direct bearing on the analysis of data.

A third set of questions is theoretical in nature:

> iii. What are the types of presuppositions or illocutionary felicity conditions that are influenced by attenuating modulations? (*see* **Presupposition**; **Pragmatic Presupposition**.) Is it possible to envisage significant connections between types of mitigation and different types of speech act felicity conditions?

Research still has to provide satisfactory answers to these questions, which need both an adequate theoretical framework and an adequate empirical grounding in different cultures/languages in different interactional contexts for different illocutionary acts. From a theoretical viewpoint, research conducted so far on various languages has shown that a systematic treatment of mitigation requires the integration of a speech act theoretical approach with other frameworks that take into account both the sequential dimension of discourse and the type of encounter in which mitigation is enacted.

The main question (which is far from being answered) regards the co-variance of variables involved in mitigating processes. From a methodological viewpoint, a first typological distinction needs to be made between form and function, between the formal means of the attenuating operation and its function in mitigation. As to form, research into various languages has shown that lexical and morphosyntactic mitigators are often employed in combination. While some mitigators are special to particular illocutions, so much so that they can be described not only as mitigating devices, but as illocutionary devices in their own right (e.g., *please* both functions as mitigator and indexes a speech act as a request), other mitigating devices can be called *passe-partout* mitigators (e.g., *a bit*, *a moment*), which are employed across a whole range of illocutions. As to function, the typologies of mitigators proposed by different authors converge in identifying, within the utterance, two abstract scopes to which the mitigating operation applies, i.e., proposition and illocution. Operating on the former, mitigation produces vagueness; operating on the latter it produces indirectness. A third scope can be added to these two, namely the deictic origin of the utterance (Bühler, 1934): the detachment of the utterance from its actual utterance source, as it happens in impersonal constructions, works, too, as a mitigating device (Haverkate, 1999). Deleting the source of the utterance and assigning it to other sources is a very frequent strategy by which speakers avoid taking responsibility for their speech acts.

As to the results of mitigation (in the second sense of the term, mentioned at the outset), they are at the same time calculable and uncertain. This holds not only in the general sense that perlocutionary acts and their perlocutionary effects, not being conventionally determined, cannot be foreseen, but also in the sense that mitigating operations may produce a margin of uncertainty, even with respect to the locutionary act, i.e., the intended act of reference and predication. In this respect, a syntactically negative structure, for instance a litotes (e.g. *John is not particularly bright*) can be described as a mitigation from a formal viewpoint (cf. Giora *et al.*, 2005); however, from a functional viewpoint, it can be attenuating (similar in that to a 'true' minimization) or reinforcing (similar in that to an hyperbole), the latter function being the one assigned by classical rhetoric to this figure of speech. In addition, it is ultimately up to the hearer to work out not only the illocutionary force of the utterance, but also its propositional content (in speaker's opinion, is John too uptight for his role, a bit shy, or just dull?).

The conclusion is that the privileged object of analysis in the study of mitigation processes should be *form*, i.e., the linguistic expressions and structural patterns of discourse in a given (macro- and micro-)context. A pragmatic analysis of each of these forms, at different degrees of conventionality, will show the interplay of heterogeneous communicative dimensions.

Research Perspectives

Mitigation lies at the core of what can be called the rhetoric of everyday interaction. This rhetoric plays

out against the background of our metapragmatic awareness (*see* **Metapragmatics**), i.e., our knowledge of what is appropriate to a given communicative situation. Mitigation is a relative concept: something is always mitigated with respect to something else. Within a repertoire of possible communicative choices which shape interactional styles in activity types, some choices will be preferred. For this reason, mitigation can only be defined contextually and co-textually within the global (and locally managed) system of the interactants' mutual expectations (*see* **Context, Communicative**). Hence, mitigation raises the issue of a complex system of knowledge, encompassing attitudinal and emotive factors: about the world, about the words, about ourselves, and about our interlocutors. It can only be dealt with satisfactorily when all these aspects (macro- and micro-sociocultural, linguistic, psychological, relational) and their interplay are considered.

As a concept that captures the rhetorical, indexical quality (*see* **Deixis and Anaphora: Pragmatic Approaches**) of our communicative behaviors, mitigation cannot be fully accounted for by an exact, abstract definition or strict classification: such techniques are only possible for decontextualized units. Precisely because of its rhetorical nature, ambivalence is its inherent quality: an antiphrastic tension, even a slight paradoxical current, runs through mitigation. After all, if someone mitigates, it means that there is something to be mitigated: where everything is (interactionally) 'safe,' there is no need of mitigation.

So far, mitigation has been a subtopic of the wide field of research in politeness and its dominating metaphor of 'face.' In Caffi (1999, 2001, and forthcoming), an extended view of mitigation is put forward: mitigation is defined as a weakening of one or more heterogeneous interactional variables (e.g., commitment to the proposition, degree of (in)directness of the illocution, endorsement of a social role, emotive involvement, topical salience, etc.), which constitute the system of an encounter. The predominant currents in pragmatics have been sociologically oriented. In accordance with their emphasis on the cultural and social aspects of the construction and negotiation of meaning, the notion of mitigation as a type of strategic behavior in a goal-oriented activity has been foregrounded. What so far has remained in the background is the psychological side of this meaning-construction that can be summed up in the question: In a given encounter, what kind of person would I like to be taken as? What is the relationship between the use of different types of mitigation and speakers' constructions of the 'self,' i.e., their self-presentations beyond mere face-work? What is the impact of mitigated choices on the process of interlocutors' mutual attunement (Caffi, forthcoming)? An integrated approach does not dismiss the sociological view, but emphasizes the need to take the personal, psychological, emotive dimension into account. The model speaker of pragmatics is, at present, a *face*. This 'face' should be seen as belonging to a *person*, viz., a complex speaking subject endowed with a metapragmatic awareness covering social as well as cognitive and emotive discursive competences. In mitigating processes, there seems to be another motivational factor, more basic than politeness, i.e., minimizing responsibility. By mitigating, a speaker can avoid running unnecessary risks. Once again, it becomes clear that 'saying is doing'; as a type of doing, saying presupposes rights, implies risks, triggers obligations, produces effects, and changes contexts. Far from being relegated to some kind of stylistic variation (*see* **Style**) or assigned to some province of (classic or new) rhetoric, mitigation is directly linked to the optimization of the system triggered by an encounter; it smooths out the interactional processes by presenting the speaker as considerate, tactful, thoughtful, and empathetic, and thus makes the attainment of interactional goals easier. In conclusion, mitigation both presupposes and reaffirms the multidimensional character of actual discursive choices, and foregrounds our identities both as social actors and as interacting persons.

Background

The notion 'part of speech' has been a central feature of the Western linguistic tradition from the beginning. The classical grammatical tradition, rooted in Aristotle (384–322 B.C.) and the grammars of Dionysius Thrax (c. 170–c. 90 B.C.) and Aelius Donatus (fl. 353 A.D.), left us with eight parts of speech: the verb, the noun, the pronoun, the adjective, the adverb, the preposition, the conjunction, and the interjection.

This traditional view has been carried over to modern generative grammar, in which it is assumed that there is a small number of primitive, probably universal, probably innate grammatical categories (Chomsky, 1965: 65):

> The question of substantive representation in the case of the grammatical formatives and the category symbols is, in effect, the traditional question of universal grammar. I shall assume that these elements too are selected from a fixed, universal vocabulary, although this assumption will actually have no significant effect on any of the descriptive material to be presented.

This marks a break from earlier American structuralist methods, in which the problems with naively applying the traditional part of speech distinctions to typologically diverse languages were well known. Whorf (1945: 1) warned that "the very natural tendency to use terms derived from traditional grammar,

Mixe-Zoquean Languages

R A Rhodes, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

The Mixe-Zoquean languages are found in southern Mexico in the area of the Isthmus of Tehuantepec. The family is divided into two branches, Mixe languages in the Oaxacan highlands and the Zoquean languages, which are found on the Gulf of Mexico and in western Chiapas. The languages are:

- Zoquean
  - Gulf Zoque
    - Sierra Popoluca
    - Texistepec
    - Ayapa Zoque (Tabasco Zoque)
  - Southern Zoque
    - Chimalapa
    - Copainalá
    - Francisco León
    - Zoque de Rayón
- Mixean
  - Veracruz Mixe
    - Oluteco (Oluta Popoluca)
    - Sayuleño (Sayula Popoluca)
  - Highland Mixe
  - Western Mixe
    - Totontepec
    - Tlahuitoltepec
  - Eastern Mixe
    - Coatlán
    - Isthmus
    - Quetzaltepec
    - Juquila
    - Mazatlán

The Southern Zoque region of western Chiapas and the Highland Mixe region are dialect chains, such that the number of dialects and varieties is unevenly reported. The division given above represents varieties that show significant differentiation as measured by degree of mutual intelligibility (Grimes, 2004).

Historically, the ancestors of the Mixe-Zoqueans were the Olmecs (Campbell and Kaufman, 1988). This once controversial assertion was proved in the 1990s with the decipherment of Epi-Olmec hieroglyphics by Terry Kaufman and John Justeson, who have shown incontrovertably that the language represented is Zoquean (Kaufman and Justeson, 2003).

Phonology

The most salient phonological patterns of the Mixe-Zoquean languages are best understood through the

phonological patterns of the protolanguage. Proto-Mixe-Zoquean had a six-vowel system, both long and short.

i	*ɨ*	*u*
e	*a*	*o*

The consonantism was

p	*t*	*ts*	*k*	*ʔ*
m	*n*			
	s			*h*
	(l)			
		j	*w*	

The basic shapes of proto-Mixe-Zoquean roots are:

CVC	**tik*	'house'
CVCC	**niːʔh*	'water'
CVCV	**niːwi*	'chile'
CVCCV	**tahpi*	'hawk'
CVCVC	**kiʔak*	'sandal'
CVCCVC	**pistik*	'flea'

The possible first consonants of these root internal clusters are very limited, *ʔ*, *h*, *s*, and nasals. There is one further pattern that exists only in verb roots. The (ʔ)C[sib] cluster allows only *p* and *k* as the medial consonant.

CV(ʔ)C[sib]-	**heps*-	'shovel'

The phonotactics of proto-Mixe-Zoquean words allow a full array of clusters as a result of morphemic combination.

There were four phonological patterns in Proto-Mixe-Zoquean that leave significant reflexes in the modern languages. The first pattern featured metathesis of glottal stop to the front of a consonant cluster in word internal construction. When that metathesis crossed an obstruent, the obstruent was voiced. This is still an active process in some Zoquean languages, as shown in (1), and has left frozen traces in Mixean as in (2).

(1) Sierra Popoluca (Zoque)

(a)	*ʔaʔniʃpa*		'I see him/her'
	ʔan	*-ʔiʃ*	*-pa*
	1ERG	**-see**	-INCOMP
(b)	*tigiʔjpa*		'he has a house'
	Ø	*-tik*	*-ʔiʔj*	*-pa*
	3ABS	-house	**-have**	-INCOMP

(2) Sayuleño (Mixe)

ˈtigɨjp		'he enters'	
Ø	*-ˈtik*	*-ʔij*	*-p*
3ABS	-house	**-VERBALIZER**	-INCOMP

In the second pattern in syllable coda obstruents were augmented with a preceding *h*. The reflexes of this pattern yield allomorphies of morphemes with and without coda *h*s in both Zoquean and Mixean languages, although in most languages the patterns are radically restructured. In a few languages, including Sierra Popoluca and Oluta, the pattern was leveled away.

(3) Francisco León Zoque

(a)	***petpa***		'he sweeps'
	Ø	***-peht***	*-pa*
	3ABS	-sweep	-INCOMP
(b)	***pehtu***		'he swept'
	Ø	***-peht***	*-u*
	3ABS	-sweep	-COMP

In Sayuleño (Mixe) the restructured pattern is one of *h* metathesis, as shown in (4).

(4) Sayuleño (Mixe)

niˈʔeʔhpɨp			'he sees himself'	
Ø	*-ni*	*-ˈʔeʔp*	***-hɨ***	*-p*
3ABS	-REFL	-see	**-MIDDLE**	-INCOMP

The third pattern affected a class of roots containing VːʔC. In construction with a consonant initial suffix the glottal was deleted. In construction with a vowel initial suffix the glottal was retained. This allmorphy has been leveled away in Zoquean.

(5) preconsonantal prevocalic/preglide

(a) Oluteco (Mixe)

ˈmimpa	'he comes'	***miʔn***	'come'	
Ø	***-ˈmiːʔn***	*-pa*	***ˈmiːʔn***	*-ɨ*
3ABS	-come	-INCOMP	come	-IMP

(b) Totontepec (Mixe)

diˈpɛːtp	'I sweep it'	
di	*-ˈpɛːʔt*	*-p*
3ERG	-sweep	-INCOMP
diˈpeʔ	'(that) I sweep it'	
di	*-ˈpɛːʔt*	*-I*
3ERG	-sweep	-INCOMP_DEP

The last pattern in the phonology of the protolanguage featured a limited height harmony in a few suffixes. The reflexes remain most clearly in the Zoquean languages.

(6) Copainalá Zoque

haʔn	*mini*		'he doesn't come'
haʔn	*j*	*-min*	***-i***
NEG	3ABS	-come	**-NEG.INCOMP**
haʔn	*mjone*		'he doesn't wrap it'
haʔn	*j*	*-mon*	***-i***
NEG	3ABS	-wrap	**-NEG.INCOMP**

Much of Mixean has lost unstressed vowels. One effect is that vowels were lost from final syllables. One of the key phonological developments related to this vowel loss is that the Highland Mixe languages developed an umlaut that expanded the vowel systems in some dialects to three-height nine vowel systems with higher vowels triggered by suffixes that had high vowels.

(7) Totontepec Mixe
(a) normal
ʃɛhp 'I breathe' (< **ʔiˈʃehpa*)
Ø *-ʃɛh* *-p*
1ABS-breathe-INCOMP
raised
nʒeh '(that) I breathe' (< **ʔinˈʃehi*)
n *-ʃɛh* *-I*
1ABS_DEP-breathe-INCOMP_DEP
(b) normal
tʊːmp 'I work' (< **ʔiˈtuːmpa*)
Ø *-ˈtʊːn* *-p*
1ABS-work-INCOMP
raised
ndun '(that) I work' (< **ʔinˈtuːni*)
n *-ˈtʊːn* *-I*
1ABS_DEP-work-INCOMP_DEP

Syllable coda *w*s in Zoquean are nasalized to *ŋ*. In all varieties the alternation is at least partially leveled leading to a marginal contrast.

(8) Copainalá Zoque
tsiŋba 'he bathes' *tsiŋu* 'he bathed'
Ø *-tsiŋ* *-pa* *Ø* *-tsiŋ* *-u*(*-u* < **wi*)
3ABS -bathe -INCOMP 3ABS -bathe -COMP
tsiwi 'bathe!'
tsiŋ *-i*
bathe -IMP
(cf. Say. *chiwjahpa* 'they bathe')

There are two other phonological developments in the Zoquean branch that are typologically notable. Most varieties of Zoque have lost vowels from initial person markers. The result is those that contain *i* historically synchronically contain *j*, which metathesizes to the onset final position. This metathesis generalizes to other *j*C clusters.

(9) Copainalá Zoque
mbjopjamih 'you (sg.) are running'
nj *-poj* *-pa* = *mih*
2ABS -run -INCOMP = 2

Finally, Texistepec has undergone a typologically unusual sound change, denasalizing root initial nasals in nonnasal environments, e.g., *bok* 'maize,' *dʲeːw* 'chile,' cf. Copainalá *mok*, *niwi*.

Morphology

The Mixe-Zoquean languages are agglutinative, as exempified in (10), and they show extensive compounding, as in (11).

(10) Sierra Popoluca (Zoque)
ʔitʲiʔŋ o ʔjkaʔa ʔjnepa 'he$_i$ is cutting with his$_j$ instrument'
ʔi *-tiŋ* *-ʔoʔj* *-kaʔ* *-ʔaʔj* *-ne* *-pa*
3ERG -cut -ANTI -INST -APPL -PROG -INCOMP

(11) Coatlán Mixe
tsahptihk 'church'
tsahp *-tihk*
sky -house

The family also shows widespread cliticization, for example, the person clitics in the Copainalá verb complex in (12a) and the stressed clitics of Sayuleño.

(12) (a) Copainalá Zoque
*mbjoju**mih*** 'you ran'
nj *-poj* *-u* = ***mih***
2ABS -run -COMP = **2ABS**
***nimih** mbjoju* 'you are running'
ni = ***mih*** *nj* *-poj* *-u*
PROG = **2ABS** 2ABS -run -DEP
(b) Sayuleño (Mixe)
ˌtikˈnaʔ 'the house'
ˈtik = *ˈnaʔ*
house = **DEF_(NON-FEM)**
ˌniʃˈpej 'he is going, too'
ˈniʃ *-p* = *ˈ**ej***
go -INCOMP = **also**

Mixe-Zoquean languages have two inflectional classes, nominal and verbal. Adjectivals are inflected like nominals.

Nominals inflect for number and possessor, and in southern Zoque, for case. The cases are absolutive and ergative/genitive.

(13) (a) number
ˈtihkat 'houses' Sayuleño (Mixe)
*ˈtik-**hat***
house-**PL**
(b) possessor
ŋguj 'my stick' Texistepec (Zoque)
n *-kuj*
1POSS -stick/tree
(c) case
pin 'man (*abs*)' Copainalá Zoque
*piʔ**nis*** 'man (*erg/poss*)'

Nominals also have derivational forms with adpositional meanings, many built on reflexes of the protomorpheme **-mi* 'locative.' There are more adpositionals in southern Zoque and fewer in Mixe.

(14) Francisco León Zoque
*kumguʔ**jomo*** 'in/to the town'
*kumkuj-**ʔomo***
town-**LOC**

Verbs inflect for aspect, subordination, and person and number of both subject and object.

The aspects are incompletive and completive with allomorphs registering subordination. Most languages also have forms for future. In Zoque, the subordinate forms are only used in auxiliary constructions.

(15) (a) Oluta (Mixe)

	independent	subordinate	
incompletive	*tiˈkajp*	*tinˈkaje*	'I am eating'
completive	*tiˈkaju*	*tinˈkaji*	'I ate'
future	*tiˌkaˈjam*	*tinˌkaˈjaʔn*	'I will eat'

(b) Copainalá Zoque

independent	subordinate
popjaʔih	*haʔnih mboje*

'I'm running'/ 'I'm not running'

pojuʔih	*hapjojaʔih*

'I ran'/ 'I didn't run'

maŋbaʔih poju	–

'I will run'

The persons are first, second, and third, with a contrast of inclusive and exclusive in the first person plural.

(16) Sierra Popoluca (Zoque)

	singular		dual
'I go'	*ʔanikpa*		
		'you and I go'	*tanikpa*
'you (sg.) go'	*miɲikpa*		
'he/she goes'	*nikpa*		
		plural	
	'we (ex.) go'	*ʔanik taʔmpa*	
	'we (in.) go'	*tanik taʔmpa*	
	'you (pl.) go'	*miɲik taʔmpa*	
	'they go'	*nikyahpa*	

Transitive verbs are marked inflected for both subject and object (or ergative and absolutive).

(17) Sierra Populca

	'… me'	'… you'	'… him'
'I love :'	–	*miɲtʲojpa*	*ʔantojpa*
'you love :'	*ʔantojpa*	–	*ʔiɲtʲojpa*
'he loves :'	*ʔatojpa*	*mitʲojpa*	*ʔitʲojpa*

In the Mixean branch there is inversive person marking, including some true inverse systems, as in Sayuleño. Such systems contain two distinct transitive forms for third person acts on third person, a direct form in which the subject is in focus and an inverse form in which the object is in focus. The Sayuleño system is based on a person hierarchy that ranks first person above second person above third person. The inverse marker in Sayuleño is *-ʃ-*, which has the third person allomorph *-gi-*.

(18) Sayuleño (Mixe)

	'… me'	'… you'	'… him'
' I hit …'	–	*tiˈmojp*	*tinˈmojp*
'you hit …'	*ʔiʃmojp*	–	*ʔinˈmojp*
'he hits …'	*tiʃmojp*	*ʔiʃmojp*	*ʔiˈmojp* (direct)/ *ʔigiˈmojp* (inverse)

As in some other Meso-American language families, there is a special class of verbs that are used to refer to the positions of people and objects. These are built on the reflexes of the derivational suffix **-nay-*. In most cases, the lexical roots found in this construction cannot be used in other combinations. The positions referred to are frequently semantically complex.

(19) Sayuleño (Mixe)

ˈwehnap	'he sits with his legs apart'	
ˈweh	*-naY*	*-p*
sit with legs apart	-POSITIONAL	-INCOMP

Syntax

The syntax of the Mixe-Zoquean family is typologically typical of Meso-American. Most of the languages are headmarking ergative, with VSO word order.

(20) Copainalá

jahkiʔmu		*jomoʔs*	*teʔ sapane*	
j - jah - kiʔm - u		*jomo -ʔs*	*teʔ sapane*	
3ERG - CAUS - go_up - COMP		woman-ERG	DEFbanana	
V		S	O	
paktihkohmo	*waʔy*	*kjiŋu*		
paktihk - ohmo	*waʔy*	*j - kiŋ - u*		
attic- LOC adv	that	3ABS - ripen - DEP		

'The woman took the bananas to the attic to ripen.'

The syntax of dependent verb forms differs between the two branches of the family. The Zoquean languages use the dependent inflections only in construction with auxiliaries. The Mixean languages have a wider variety of constructions triggering dependent inflection, for example, in clauses with fronted adverbials.

(21) Totontepec Mixe

yam	*ʔəts*	*mpəːʔkʃ*
ˈyam	*ˈʔəts*	***n***
here	1	**1ABS_DEP**

'I'm resting here.'

-ˈpəːʔkʃ	*-Ø*
-rest	**-INCOMP_DEP**

In auxiliary constructions, the auxiliary has third singular subject and bears the aspect. The lexical verb bears the subject person/number marking and incompletive dependent aspect.

(22) Sayuleño

kiʃp naʃˈkajga	
Ø -ˈkiʃ -p	***naʃ***
3ABS-finish-**INCOMP**	**1INCL_ERG_DEP**

'We (incl.) finished eating.'

*-ˈkaj-**ka**-**Ø***
-eat-**PL-INCOMP_DEP**

Object incorporation is widespread throughout the family.

Distinguishing the Branches

Phonological development distinguishes the two branches of the family. Zoquean underwent two

significant developments. First, the length contrasts were leveled.

(23)	Mixean		Zoquean		
	Sayuleño	Totontepec	Copainalá	Texistepec	
	moːhk	*mɔːhk*	*mok*	*bok*	'maize'
	tiːhts	*təːts*	*tits*	*tɨts*	'tooth'

The contrastive length in Gulf Zoquean is a secondary development. The first syllable of disyllabic roots is lengthened if it is underlyingly open, e.g., Sierra Popoluca *kaːma*, Copainalá *kama* 'cornfield,' proto-Mixe-Zoquean **kama*. Second, a class of proto-Mixe-Zoquean CVːʔC roots show glottal allomorphy in Mixe, which was leveled to CVC roots in Zoquean.

(24)	Mixean		Zoquean	
	Sayuleño	Coatlán	Copainalá	Sierra Popoluca
	ʔuːkp	*ʔʊːkp*	*ʔukpa*	*ʔukpa* 'he drinks'
	ʔuʔk	*ʔuʔuk*	*ʔukɨ*	*ʔuːkiʔ* 'drink *imp*'

There are a few regular morphological features that distinguish Mixean from Zoque, for example, the future. Throughout the Mixean branch, the future is formed on the reflexes of a verbal compound with the stem *waːʔn*-'want'. In Gulf Zoque the future is one of the meanings of the incompletive forms (*-pa*). In Southern Zoque, futures are auxiliary constructions.

(25)	Mixean		Zoquean	
	Sayuleño	Coatlán	Copainalá	Sierra Popoluca
	ˌʔuʔˈkam	*ˈʔʊʔʊkʊp*	***maŋ***	***baʔuhku*** 'hewilldrink' *ʔukpa*

A number of common words or usages also distinguish the two branches.

(26)	Mixean		Zoquean		
	Sayuleño	Coatlán	Copainalá	Sierra	Popoluca
	ʃɨhw	*ʃɨː*	*hama*	*haːma*	'sun, day'
	ʔɨˈwamp	*jwaːmb*	*ʃumpa*	*ʔɨʃumpa*	'he wantsit'
	ˈtoʔʃaj	*ˈtoʔʃjhaɾj*	*jomo*	*joːmo*	'woman'

Mobilian Jargon

E Drechsel, University of Hawai'i at Mānoa, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Mobilian Jargon or the Chickasaw-Choctaw trade language was a Muskogean-based pidgin of the lower Mississippi River valley, typologically comparable (although unrelated) to Chinook Jargon of northwestern North America. Not to be confused with Mobilian proper of southern Alabama, whose genetic classification has remained in doubt until today, Mobilian *Jargon* (MJ) was a structurally and functionally reduced contact medium that drew principally on Muskogean as its source languages. MJ displayed a characteristic Muskogean phonology,

Background

The notion 'part of speech' has been a central feature of the Western linguistic tradition from the beginning. The classical grammatical tradition, rooted in Aristotle (384–322 B.C.) and the grammars of Dionysius Thrax (c. 170–c. 90 B.C.) and Aelius Donatus (fl. 353 A.D.), left us with eight parts of speech: the verb, the noun, the pronoun, the adjective, the adverb, the preposition, the conjunction, and the interjection.

This traditional view has been carried over to modern generative grammar, in which it is assumed that there is a small number of primitive, probably universal, probably innate grammatical categories (Chomsky, 1965: 65):

> The question of substantive representation in the case of the grammatical formatives and the category symbols is, in effect, the traditional question of universal grammar. I shall assume that these elements too are selected from a fixed, universal vocabulary, although this assumption will actually have no significant effect on any of the descriptive material to be presented.

This marks a break from earlier American structuralist methods, in which the problems with naively applying the traditional part of speech distinctions to typologically diverse languages were well known. Whorf (1945: 1) warned that "the very natural tendency to use terms derived from traditional grammar,

like verb, noun, adjective, passive voice, in describing languages outside of Indo-European is fraught with grave possibilities of misunderstanding." Sapir (1921: 118) clearly rejects the notion of parts of speech as syntactic primitives:

> A part of speech outside of the limitations of syntactic form is but a will o' the wisp. For this reason, no logical scheme of the parts of speech – their number, nature, and necessary confines – is of the slightest interest to the linguist.

More moderately, Bloomfield (1933: 196) warned against what he saw as the practice of traditional grammarians:

> The term *parts of speech* is traditionally applied to the most inclusive and fundamental word-classes of a language, and then . . . the syntactic form classes are described in terms of the parts of speech that appear in them. However, it is impossible to set up a fully consistent set of parts of speech, because the word-classes overlap and cross each other.

Bloomfield here was not arguing against a set of either universal or language particular parts of speech but against the very idea of parts of speech as anything but vague generalizations across overlapping word classes.

Gerunds

For the most part, the structuralists' concerns have not played a major role in the development of generative grammar because the notion of lexical category is central to grammatical theory. Since the advent of generative grammar, linguists have made considerable progress in the understanding of language and, not surprisingly, the traditional inventory of parts of speech has proven to be sufficient for the analysis of most constructions in English and for a broad range of other languages. However, there is a class of constructions, known as transcategorial or simply mixed category constructions, that do not fit well with any refinement of the four basic categories. These constructions involve lexical items that seem to be core members of more than one category simultaneously. A well-known example is the English verbal gerund, which combines with both a direct object (like a verb does) and a genitive possessor (like a noun does).

English has a wide range of nominalization constructions, a few of which are demonstrated in (1):

(1a) the DA was shocked **that Pat illegally destroyed the evidence**
(1b) the DA was shocked by **Pat having illegally destroyed the evidence**
(1c) the DA was shocked by **Pat's having illegally destroyed the evidence**
(1d) the DA was shocked by **Pat's illegal destroying of the evidence**
(1e) the DA was shocked by **Pat's illegal destruction of the evidence**

As these examples show, the uses of words roughly fall along an apparent continuum that ranges from fully nounlike uses to fully verblike uses. The examples in (1b–c), the verbal gerunds, are intermediate cases that do not have all the characteristics of either nouns or verbs but seem to fall somewhere in between these two categories. These constructions simultaneously show some of the properties of noun phrases and some of the properties of verb phrases. Thus, they pose a potential problem for the tradition conception of parts of speech.

Verbal Gerunds as Nouns

The strongest evidence for the nominal nature of verbal gerunds comes from the external distribution of verbal gerund phrases (VGPs). Like NPs, VGPs can appear as direct arguments of finite verbs:

(2a) Pat('s) getting arrested alarmed Chris
(2b) Chris witnessed Pat('s) getting arrested

Although many phrase type can occur as a complement, VGPs appear in contexts in which otherwise only NPs can occur. For example, complement clauses, unlike NPs, are generally prohibited from occurring sentence internally:

(3a) *I believe that Pat took a leave of absence bothers you.
(3b) *Why does that Pat took a leave of absence bother you?
(3c) *It's that Pat took a leave of absence that bothers you.

However, VGPs are subject to no such constraint:

(4a) I believe that Pat('s) taking a leave of absence bothers you.
(4b) Why does Pat('s) taking a leave of absence bother you?
(4c) It's Pat('s) taking a leave of absence that bothers you.

Similarly, VGPs can occur as the object of a preposition, a context clauses are normally barred from:

(5a) Pat is concerned about Sandy('s) getting arrested.
(5b) *Pat is concerned about (that) Sandy got arrested.

On the other hand, there are contexts that admit verbal gerunds but not regular NPs:

(6a) There's no use (you/your) telling him anything.

(6b) Your idea is worth (him/his) giving further thought to.

These constructions that require a verbal gerund provide evidence that verbal gerunds form a subcategory of noun distinct from common nouns.

Verbal Gerunds as Verbs

Although the external syntax of verbal gerunds is much like that of NPs, their internal structure is more like that of VPs. In particular, VGPs have roughly the same internal syntax as a nonfinite VP headed by the same verb. For one, verbal gerunds take adverbial modifiers. In contrast, true nouns take adjectival modifiers:

(7a) Pat didn't expect me to *quiet/quietly leave before anyone noticed.
(7b) Pat disapproved of (me/my) *quiet/quietly leaving before anyone noticed.
(7c) Pat disapproved of my quiet/*quietly departure.

Similarly, verbal gerunds can be negated with the particle *not,* but *not* cannot in general be used to negate a noun:

(8a) It's unusual for Pat not to have bathed for a week.
(8b) Pat's not having bathed for a week disturbed the other diners.
(8c) *The not processing of the election results created a scandal.

Also, verbal gerunds take accusative NP complements, whereas the nominal gerund in (9c) can only take a PP complement:

(9a) Pat diligently calls the roll each day.
(9b) (Pat's/Pat) diligently calling (*of) the roll started each day.
(9c) The diligent calling *(of) the roll started each day.

Furthermore, the verbal gerund, unlike the nominal gerund, has the same selectional properties as the corresponding main verb:

(10a) Chris casually put the roast in the oven.
(10b) Chris's/Chris casually putting the roast in the oven appalled the visiting vegetarians.
(10c) Chris's casual putting of the roast in the oven appalled the visiting vegetarians.

This extends even to derived subcategorization frames, such as the passive or the resultative:

(11a) Pat was helped by Sandy.
(11b) Pat's being helped by Sandy made all the difference.
(11c) Lee hammered the sheet flat.
(11d) Lee's hammering the sheet flat made a terrible noise.

Types of Verbal Gerunds

To summarize, VGPs have four basic properties that need to be accounted for:

1. A verbal gerund takes the same complements as the verb from which it is derived.
2. Verbal gerunds are modified by adverbs and not by adjectives.
3. The entire VGP has the external distribution of an NP.
4. The subject of the gerund is optional and, if present, can be either a genitive or an accusative NP.

Properties 1–4 are shared by accusative subject (ACC-*ing*), genitive subject (POSS-*ing*), and subjectless (PRO-*ing*) verbal gerund phrases and are not shared by any other English constructions. The three types of verbal gerunds seem to be subtypes of a single common construction type, and any analysis of verbal gerunds ought to be able to account for their similarities in a systematic way.

It is important to note, however, that there are differences among the three types that also must be accounted for. The most obvious difference is the case of the subject. In this and a number of other respects, POSS-*ing* phrases are more like NPs, whereas ACC-*ing* phrases are more like Ss (Reuland, 1983; Abney, 1987; Malouf, 2000). For example, as Abney (1987) observed, POSS-*ing* but not ACC-*ing* VGPs with *wh* subjects can front under 'pied piping' in restrictive relative clauses:

(12a) The person whose being late every day Pat didn't like got promoted anyway.
(12b) *The person who(m) being late every day Pat didn't like got promoted anyway.

The same contrast can be seen between genuine NPs and Ss:

(13a) The person whose chronic lateness Pat didn't like got promoted anyway.
(13b) *The person (for) who(m) to be late every day Pat didn't like got promoted anyway.

What these examples show is that although all VGPs show a mixed of nominal and verbal properties, some are slightly more verbal, whereas others are slightly more nominal.

Theoretical Approaches

Any grammatical theory that places any importance on parts of speech must account for the basic properties of verbal gerunds (Table 1).

The earliest generative analyses of English verbal gerunds took a brute-force approach to accounting

Table 1 Properties of verbs, verbal gerunds, and nouns

Verb	*Verbal gerund*	*Noun*
Govern NP complements	Govern NPs	Don't govern NPs
Adverbs	Adverbs	Adjectives
Subjects	Subjects/ specifiers	Specifiers
Occur with _Not_	Occur with _Not_	Don't occur with _Not_
S distribution	NP distribution	NP distribution

Figure 1 Structure from which POSS-*ing* gerund is derived.

for these facts and treated them as exocentric constructions. To take one example, Jackendoff (1977) proposed the exceptional rule schema in (14a) for nominalizations, in which (14b) is an instantiation of for POSS-*ing* gerunds:

(14a) $X^i \rightarrow \text{Aff } V^i$
(14b) $N'' \rightarrow$ *-ing* V''

A POSS-*ing* gerund such as *Pat's watching television* would be derived from a structure like that in Figure 1. The affix *-ing* then lowers onto the verb via some variation of Affix Hopping. Although this analysis captures some of the basic facts of the gerund construction, it misses an number of important generalizations. By treating the verbal gerund as an exocentric construction, it fails to account for its mixed verbal and nominal character.

Phrasal Nominalization Approaches

In an effort to assimilate the syntax of verbal gerunds to the general properties of nominal and verbal projections in English, Abney (1987) proposed an analysis of English gerunds based on affixation of the abstract nominalizing morpheme *ING* to the *-ing* form of a verb. Abney assumed that categories are marked for three features: ±N, which distinguishes nouns from verbs; a feature ±F, which

Figure 2 *ING* combining with a lexical verb to produce an N.

distinguishes lexical from functional categories; and a multivalued feature for bar level. The properties of English gerunds then follow from the assumption that *ING* bears the feature specification [+N] but is unmarked for F and bar level. When *ING* combines with a lexical verb, it inherits the verb's values for F and bar level, producing an N (Figure 2). This means that nominal gerunds will have all the syntactic properties of underived common nouns.

When *ING* affixes to a higher verbal projection, the result is a verbal gerund, either POSS-*ing* or ACC *-ing* (Figure 3). Abney correlated the degree of nominalization with the scope of the nominal affix *ING*: The higher the attachment of *ING*, the more verbal properties the phrase will have. In Figure 3A, *ING* combines with the VP *singing the Marseillaise*. VP is a nonfunctional maximal projection; VP plus *ING* is a nonfunctional maximal nominal projection, also known as an NP. Because the subject is outside the nominalized part of the VGP, it takes genitive case. In Figure 3B, *ING* combines with the entire IP *John singing the Marseille*. IP is a functional maximal projection, so IP plus *ING* is a functional maximal nominal projection, or a DP.

Abney's analysis relies on *ING*, an abstract, phonologically null nominalizing clitic. Developing this intuition further, Kaiser (1999) took an explicitly morphological approach to the problem. Kaiser's analysis is framed in Anderson's (1992) theory of A-morphous Morphology, in which derivational and inflectional morphology is handled via Word Formation Rules (WFRs) that map one lexical form onto another. As the phrasal equivalent of word-level morphology, phrasal clitics are analyzed using a similar device, the Clitic Placement Rule (CPR). Most of the clitics that Anderson discussed are inflectional, but if clitics reflect phrase-level morphology, then we would expect to find derivational clitics as well.

Figure 3 *ING* affixing to a higher verbal projection to produce a verbal gerund, either (A) POSS-*ing* or (B) ACC-*ing*.

Taking this as a point of departure, Kaiser (1999) proposed the derivational clitic placement rule for English POSS-*ing* gerunds in Table 2. This rule places the clitic-*ing* on the head of a verb phrase and changes the category of that verb phrase to NP.

Table 2 Derivational clitic placement rule

CPR	[. . . [. . .]v^0 . . .] VP → [. . . [. . . *ing*]v^0 . . .]NP
Phonology	The clitic -*ing* is realized rightmost within the domain [. . .]v^0
Syntax	VP is directly converted into NP

Source: Kaiser (1999).

Mixed Projection Approaches

In English, the putative nominalizing clitic is phonologically null. However, in some languages with overt nominalization morphology, the relevent suffix can be shown to be lexical and not phrasal. For example, Quechua has a number of nominalization constructions, one of which, exemplified in (15) (Lefebvre and Muysken, 1988: 16, 15), is comparable to the English POSS-*ing* gerund.

(15a) Manuil Pidru-man libru-ta qu-n
Manuel Pedro-DAT book-ACC give-3
'Manuel gives Pedro the book'

(15b) Manuil-pa Pidru-man libru-ta
Manuel-GEN Pedro-DAT book-ACC
qu-sqa-n-ta yacha-ni
give-NMLZ-3-ACC know-1
'I know that Manuel gives the book to Pedro'

The subject of the nominalized verb is marked like the possessor in an NP, and the complements of the nominalized verb are marked just like the complements of the equivalent finite verb would be. Unlike the English POSS-*ing* gerund, this construction has an overt morphological marker, the nominalizing affix -*sqa*-.

This nominalizing affix -*sqa*- is a good candidate for being an overt analog to the covert English nominalizer *ING*. However, Lefebvre and Muysken (1988: 82) gave numerous arguments that -*sqa*- and the other Quechua nominalizers must be treated as lexical affixes and not as phrasal clitics. For one, if -*sqa*- is a clitic then the agreement and case markers that follow it must also be clitics (Zwicky and Pullum, 1983). But, Lefebvre and Muysken showed that, in contrast to the genitive clitic -*qpa*, the accusative marker -*ta* must be an affix.

In order to account for the lexical nature of nominalizing morphology in some languages, as well as to preserve lexical integrity for English gerunds, Pullum (1991) proposed an analysis of verbal gerunds that exploits the flexibility of the Generalized Phrase Structure Grammar (Gazdar *et al.*, 1985) Head Feature Convention (HFC) to allow V to project NP under certain circumstances. Pullum (1991) started with the following rule for ordinary possessed NPs:

(16) N[BAR:2] → N[BAR:2, POSS:+], H[BAR:1]

The head of the phrase is specified only for the feature BAR. The HFC is a default condition that requires that the mother and the head match on all features, as long as they do not conflict; for instance, for the rule in (16) this ensures that the head will match the mother in its major category and that the phrase will be headed by an N. Given these assumptions, Pullum observed that POSS-*ing* VGPs may be accounted for by a slightly modified version of the previous rule:

(17) N[BAR:2] → (N[BAR:2, POSS:+])
H[VFORM:prp]

This rule differs from the rule in (16) only in the feature specification on the head daughter: In (17), the head daughter is required to be [VFORM:prp]. An independently motivated constraint that requires that any phrase with a VFORM value must be verbal overrides the HFC, so the rule in (17) will only admit phrases with -*ing* form verb heads. However, the

Figure 4 Verbal gerund structure, application of rule (17).

left-hand side of the rule is the same as the left-hand side in (16), so (17) gives verbal gerunds the structure in Figure 4. This reflects the traditional description of VGPs as 'verbal inside, nominal outside' quite literally by giving verbal gerund phrases a VP node dominated by an NP node.

However, as Lapointe (1993) observed, there are at least three problems with Pullum's analysis. The first problem is that it leaves very little content to the notion of a phrasal 'head,' yielding rules that are very similar to those proposed under the headless gerund analyses such as Jackendoff's. Another problem is that it has no way of representing that some types of mixed category constructions are much more common than others. Nothing in it prohibits outlandish and presumably nonattested rules such as:

(18a) VP → H[NFORM:plur], PP
(18b) N′ → (QP), H^0 [VFORM:psp]

And, nothing in it explains why constructions parallel to the English POSS-*ing* verbal gerund are found in language after language.

To avoid these shortcomings, Lapointe (1993) (and similar analyses proposed by Wescoat, 1994); Bresnan, 1997 offered a more conservative modification to the standard notion of endocentricity. He proposed introducing dual lexical categories such as <N|V>, a V that projects a VP dominated by an NP. This approach avoids some of the problems associated with default projection by restricting the conditions under which 'changeover' from nominal to verbal projection can occur.

Mixed Category Approaches

The analyses described in the previous section account for the hybrid properties of mixed category constructions by positing mixed nominal and verbal syntactic projections. In contrast, the approach taken by Malouf (2000), along with the similar proposals by Francis (1999) and Hudson (2003), offered a strictly lexical account of verbal gerund's mixed behavior. It did this by factoring syntactic properties into separate categorial, selectional, and

Figure 5 Malouf's (2000) structures for (A) POSS-*ing* and (B) ACC-*ing* verbal gerunds.

constructional dimensions. Categorial information, projected from the lexical head following the conventions of standard X′ theory (Chomsky, 1970), determines the external distribution of a phrase. A lexical head's selectional features, on the other hand, determine what kinds of other phrases can occur in construction with that head. Finally, constraints on particular constructions control the combination of syntactic units. Within each of these three domains, VGPs show fairly consistent behavior. What is unusual about verbal gerunds is that their lexical entries combine of nounlike categorial properties with verblike selectional properties. Given this, their distribution is fully predicted by the language's inventory of syntactic constructions.

Under Malouf's (2000) account, POSS-*ing* and ACC-*ing* verbal gerunds are assigned the structures in Figure 5. The gerund *folding* selects for a subject and a direct object, like a verb does, and it combines with its dependents via the same constructions by which a verb combines with its dependents. In one sense, under this analysis a verbal gerund together with its complements really is like VP, in that both are instances of the same construction type and both are subject to any constraints associated with that construction. In the same way, a verbal gerund plus an accusative subject really do form an S, whereas a

verbal gerund plus a genitive subject really do form an NP. This reflects the traditional view that verbal gerund phrases are built out of pieces of syntax 'reused' from other parts of the grammar. However, verbal gerunds project the categorial type Gerund, a subtype of noun. This means that the entire VGP has the external distribution of an NP.

Although Malouf (2000) formalized this approach to mixed categories using Head-Driven Phrase Structure Grammar, it is in its general outlines more in the spirit of a functionalist notion of grammatical categories. In contrast to the strictly extensional, discrete view of categories in generative grammar, functional and cognitive approaches to language have developed theories of prototype categories (e.g., Lakoff, 1987; Langacker, 1987; Croft, 1991). Quite unlike generative grammar's parts of speech, prototype categories allow gradient membership and have indistinct boundaries. Instead of sorting linguistic units into larger or smaller discrete uniform classes, functionally oriented linguists explore the variation within heterogeneous classes.

Croft (1991: 6) framed the difference between the two views of categories as a difference in the interpretation of morphosyntactic tests, "grammatical construction[s], one or more features of which define or require a specific type of linguistic unit to satisfy it or fill it." For example, in English only nouns can be pluralized through the addition of the suffix *-s*. Thus, the plural suffix can be used as a test for nounhood. We might take the occurrence with the definite article *the* as another test for nounhood in English.

Ideally, all morphosyntactic tests for a particular linguistic unit in all languages will give the same result, but this is rarely the case. Croft argued that formal and functional approaches to linguistics diverge in their reconciliation of the ideal behavior of syntactic tests with their actual behavior. Generative grammarians take certain tests to be criterial while dismissing other conflicting tests as peripheral or unreliable. This preserves the ideal view of categories as universal and discrete domains at the cost of "cut[ting] the link between the tests (i.e., features of grammatical constructions) and their domain of application (i.e., the class of linguistic units that those features admit)" (Croft, 1991: 15).

Syntactic Variation

If categories are defined in terms of their properties, rather than the other way around, then mixed category constructions pose no problem. Under this view, parts of speech as such play no role in the grammar. Instead, grammatical processes are sensitive to a number of independently varying types of information. Far from being an anomaly, some degree of categorial mixing is to be expected. In fact, we would be surprised not to find a wide variety of ways in which categorial properties can combine. However, looking at the range of variation among mixed category constructions, both within English and cross-linguistically, shows that not all possible combinations of properties are actually attested.

Table 3 Pattern of properties of nominalizations

	Finite verb	*Direct case subject*	*Adverb modifier*	*Direct case object*	*Verbal form*
a.	+	+	+	+	+
b.		+	+	+	+
c.			+	+	+
d.					+
e.					

We began the section on gerunds by considering a number of English nominalization constructions, exemplified in (1). We can differentiate these nominalization types on the basis of five properties: whether they include a finite verb, whether they take a direct case (i.e., nominative or accusative) subject, whether they allow an adverbial modifier, whether they take a direct case object, and whether they include a regularly inflected verb form. When we arrange the results, a clear pattern emerges (Table 3). Nominal and verbal properties are not arbitrarily mixed in these constructions. Rather, they can be arranged into the implicational hierarchy.

Croft (1991), drawing on Comrie (1976) and his own survey of the properties of syntactic categories in diverse languages, observed that a similar pattern comes up in other languages with several nominalization types. On this basis, he proposed a universal hierarchy:

(19) Deverbalization Hierarchy (Croft, 1991, 83)

If a verbal form inflects for tense-aspect-modality like a predicated verb, then it will take subject and object dependents like a predicated verb. If a verbal form takes a subject dependent like a predicated verb, then it will take an object dependent like a predicated verb

This generalization is confirmed by Koptjevskaja-Tamm's (1993) much more extensive and systematic cross-linguistic survey of nominalization types. Interestingly, the cross-linguistic data do not support including the choice between adverbial and adjectival modification in the hierarchy.

Although they are generally motivated on language internal grounds, analyses that involve a changeover in projection from V to N have an obvious connection to the Deverbalization Hierarchy. Lapointe (1993), Borsley and Kornfilt (2000), and Bresnan (1997)

made this link explicitly, pointing out that the attested nominalization types correspond to different levels of phrasal nominalization. Consider the structures in Figure 6. In each case, the fully nominal part of the phrase is limited to the contiguous region within the dotted line. Outside the dotted line, the phrase is fully verbal. Malouf (2000) called this explanation the Phrasal Coherence Hypothesis: the Deverbalization Hierarchy follows from the fact that in a mixed projection there must be a single point of articulation dividing the nominal part of the phrase from the verbal part. A nominalization that, say, combines with its subject like a verb does but with its complements like a noun does would have the structure as in Figure 7. In such a case, the nominal part of the phrase would be split into two regions by an intervening verbal projection, violating the Deverbalization Hierarchy.

Figure 6 In each structure, the fully nominal part of the phrase is limited to the contiguous region within the dotted line; outside the dotted line, the phrase is fully verbal.

Although the Phrasal Coherence Hypothesis explains the distribution of verbal gerunds in many languages, in some respects it appears to be too strong. Among other things, it predicts that all words associated with the nominal part of the phrases should appear outside those associated with the verbal part of the phrase. And, indeed, in many languages (including English) this prediction is borne out. When we look at verb-initial languages, however, this is not always the case.

One such language is Standard Arabic. Arabic has fairly strict noun-possessor order within noun phrases (Fassi Fehri, 1993: 223):

(20a) zur-tu ʔumm-a r-rajul-i
visited-I mother-ACC the-man-GEN
'I visited the man's mother'

(20b) *zur-tu r-rajul-i ʔumm-a
visited-I the-man-GEN mother-ACC

Any additional nominal modifiers or complements come after the possessor (Fassi Fehri, 1993: 218):

(21a) daxtal-tu daar-a r-rajul-i
entered-I house-ACC the-man-GEN
l-waasi^{c}at-a
the-large-ACC
'I entered the large house of the man'

Figure 7 Structure of a nominalization that combined with its subject like a verb does but with its complements like a noun does.

(21b) daxtal-tu daar-a r-rajul-i
entered-I house-ACC the-man-GEN
l-latii ḥtaraq-at
the-that-FEM burned-3.FEM.SING
'I entered the man's house that burned'

And this same NSO order is found in the *maṣdar* construction, comparable to the English POSS-*ing* verbal gerund (Fassi Fehri, 1993: 223):

(22a) ʔaqlaqa-nii ntiqaad-u zayd-in ᶜamr-an
annoyed-me criticizing-NOM Zayd-GEN Amr-ACC
'Zayd's criticizing Amr annoyed me'
(22b) *ʔaqlaqa-nii ntiqaad-u ᶜamr-an zayd-in
annoyed-me criticizing-NOM Amr-ACC Zayd-GEN
(22c) *ʔaqlaqa-nii ᶜamr-an ntiqaad-u zayd-in
annoyed-me Amr-ACC criticizing-NOM Zayd-GEN

This construction is the same as its English counterpart in many respects. The *maṣdar* combines with a possessor like a noun does and with a complement like a verb does, and the entire phrase has the distribution of an NP. However, unlike the English construction, the verbal part of the phrase is not strictly inside the nominal part.

This problem is especially striking when we look at modification. *Maṣdars*, like POSS-*ing* verbal gerunds, take adverbial modifiers. In Arabic, modifiers appear after the genitive subject (Fassi Fehri, 1993: 240):

(23) ʔaqlaqa-nii ntiqaad-u r-rajul-i
annoyed-me criticizing-NOM the-man-GEN
bi-stimraar-in haadaa l-mašruuᶜ-i
with-persistence-GEN this the-project-ACC
'the man's persistent criticizing of the project annoyed me'

According to a projection changeover analysis, gerunds take adverbial modifiers because they contain a partial verbal projection. This means there must be a verbal projection between the lowest nominal projection (which gives the phrase its nominal specifier) and the highest (which gives the phrase its NP distribution) (see Figure 8). However, that is exactly the structure that is ruled out by the Phrasal Coherence Hypothesis: the nominal part of the phrase is divided into two discontinuous regions.

Figure 8 Verbal projection between the lowest nominal projection (which gives the phrase its nominal specifier) and the highest (which gives the phrase its NP distribution).

Standard Arabic *maṣdars* can be given an analysis that is compatible with the Phrasal Coherence Hypothesis, if we assume that they have an underlying English-like SVO structure. Alternatively, Malouf (2000) proposed a Lexical Coherence Hypothesis, which constrains the way categorial and selection properties can combine in a single lexical entry. Under this view, *maṣdars* and gerunds have comparable lexical representations, combining the categorial features of a noun with the selectional features of a verb. The surface differences between the constructions follow from independently motivated differences in the construction inventories of the two languages.

Conclusion

Mixed category constructions such as the English verbal gerund show properties of both nominal and verbal constructions. Other mixed categories include some deverbal nouns (which are also simultaneously nominal and verbal) and participles (which are also adjectival and verbal). Any theory of parts of speech must be able to account for these apparent chimeras in a natural way.

Mixe-Zoquean Languages

R A Rhodes, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

The Mixe-Zoquean languages are found in southern Mexico in the area of the Isthmus of Tehuantepec. The family is divided into two branches, Mixe languages in the Oaxacan highlands and the Zoquean languages, which are found on the Gulf of Mexico and in western Chiapas. The languages are:

- Zoquean
  - Gulf Zoque
    - Sierra Popoluca
    - Texistepec
    - Ayapa Zoque (Tabasco Zoque)
  - Southern Zoque
    - Chimalapa
    - Copainalá
    - Francisco León
    - Zoque de Rayón
- Mixean
  - Veracruz Mixe
    - Oluteco (Oluta Popoluca)
    - Sayuleño (Sayula Popoluca)
  - Highland Mixe
  - Western Mixe
    - Totontepec
    - Tlahuitoltepec
  - Eastern Mixe
    - Coatlán
    - Isthmus
    - Quetzaltepec
    - Juquila
    - Mazatlán

The Southern Zoque region of western Chiapas and the Highland Mixe region are dialect chains, such that the number of dialects and varieties is unevenly reported. The division given above represents varieties that show significant differentiation as measured by degree of mutual intelligibility (Grimes, 2004).

Historically, the ancestors of the Mixe-Zoqueans were the Olmecs (Campbell and Kaufman, 1988). This once controversial assertion was proved in the 1990s with the decipherment of Epi-Olmec hieroglyphics by Terry Kaufman and John Justeson, who have shown incontrovertably that the language represented is Zoquean (Kaufman and Justeson, 2003).

Phonology

The most salient phonological patterns of the Mixe-Zoquean languages are best understood through the

significant developments. First, the length contrasts were leveled.

(23)	Mixean		Zoquean		
	Sayuleño	Totontepec	Copainalá	Texistepec	
	moːhk	*mɔːhk*	*mok*	*bok*	'maize'
	tiːhts	*təːts*	*tits*	*tɨts*	'tooth'

The contrastive length in Gulf Zoquean is a secondary development. The first syllable of disyllabic roots is lengthened if it is underlyingly open, e.g., Sierra Popoluca *kaːma*, Copainalá *kama* 'cornfield,' proto-Mixe-Zoquean **kama*. Second, a class of proto-Mixe-Zoquean CVːʔC roots show glottal allomorphy in Mixe, which was leveled to CVC roots in Zoquean.

(24)	Mixean		Zoquean	
	Sayuleño	Coatlán	Copainalá	Sierra Popoluca
	ʔuːkp	*ʔʊːkp*	*ʔukpa*	*ʔukpa* 'he drinks'
	ʔuʔk	*ʔuʔuk*	*ʔukɨ*	*ʔuːkiʔ* 'drink *imp*'

There are a few regular morphological features that distinguish Mixean from Zoque, for example, the future. Throughout the Mixean branch, the future is formed on the reflexes of a verbal compound with the stem *waːʔn*-'want'. In Gulf Zoque the future is one of the meanings of the incompletive forms (*-pa*). In Southern Zoque, futures are auxiliary constructions.

(25)	Mixean		Zoquean	
	Sayuleño	Coatlán	Copainalá	Sierra Popoluca
	ˌʔuʔˈkam	*ˈʔʊʔʊkʊp*	***maŋ***	***baʔuhku*** 'hewilldrink' *ʔukpa*

A number of common words or usages also distinguish the two branches.

(26)	Mixean		Zoquean		
	Sayuleño	Coatlán	Copainalá	Sierra	Popoluca
	ʃɨhw	*ʃɨː*	*hama*	*haːma*	'sun, day'
	ʔɨˈwamp	*jwaːmb*	*ʃumpa*	*ʔɨʃumpa*	'he wantsit'
	ˈtoʔʃaj	*ˈtoʔʃjhaɾj*	*jomo*	*joːmo*	'woman'

Mobilian Jargon

E Drechsel, University of Hawai'i at Mānoa, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Mobilian Jargon or the Chickasaw-Choctaw trade language was a Muskogean-based pidgin of the lower Mississippi River valley, typologically comparable (although unrelated) to Chinook Jargon of northwestern North America. Not to be confused with Mobilian proper of southern Alabama, whose genetic classification has remained in doubt until today, Mobilian *Jargon* (MJ) was a structurally and functionally reduced contact medium that drew principally on Muskogean as its source languages. MJ displayed a characteristic Muskogean phonology,

including the lateral fricative /ł/ as in /łało/ 'fish', even if the pronunciation of particular sounds ranged more widely than in Muskogean languages because of second-language interferences, and because it lacked most of their morphophonological complexities (*see* **Muskogean Languages**). Whereas early grammatical descriptions have presented MJ as a reduced form of Choctaw (Western Muskogean), it actually has revealed considerable lexical variation over space and time, reflecting the influences of its speakers' first languages. Among the primary other sources were Eastern Muskogean languages such as Alabama and Koasati and quite possibly Muskogee. Several 'exotic' loans from northern Algonquian languages with only a few from European sources suggest that MJ's range of variation extended farther north than the available linguistic evidence indicates, while remaining comparatively immune to European influences. A closer examination of MJ syntax demonstrates that whereas some constructions could derive from Choctaw or Chickasaw (Western Muskogean) equivalents, others displayed fundamental syntactic differences in need of their own explanations. (The initial dagger indicates that these MJ sentences were not actual recordings, but corresponding word-for-word *reconstitutitions* of such to match the Choctaw constructions, illustrating both the similarities and differences between the pidgin and Western Muskogean.)

(1) MJ:	†hattak	išno	pisa	taha	
	man	*you*	*see*	PAST	
Choctaw:	hattak	iš-	pisa	tuk	
	man	2 sing ACT (NOM)	*see*	PAST	

(Jacob *et al.*, 1977: 65)
'You saw a man.'

(2) MJ:	†išno	iti	ino	čali	taha
	you	*wood*	*I*	*cut*	PAST
Choctaw:	iti	chĩ-	chãli	-li	-tok
	wood	2 sing DAT	*cut*	1 sing	PAST

(Davies, 1986: 41)
'I cut wood for you.'

MJ:	†ofi	ino	banna	ino	yimmi	
	dog	*I*	*want*	*I*	*believe*	
Ch:	ofi	sa-	banna	yimmi	-li	-h
	dog	1 sing ACC (PAT)	*want*	*believe*	1 sing NOM (ACT)	PRED

(Davies, 1986: 71)
'I believe I want a dog.'

Without some means of formally marking case in words, MJ speakers could rely only on word order to identify the grammatical functions of its sentence parts, which was X/OsV and quite possibly X/OSV (with no actual attestations available for two- or multiple-argument constructions, including nominal subjects). As the above examples illustrate, MJ's unique word order probably derived from Muskogean constructions consisting of a noun plus a verb with a prefix, the latter of which speakers replaced with etymologically independent and full pronouns in their languages and which came to function as true grammatical subjects in MJ, although not necessarily as agents. MJ thus followed a grammatical pattern that was fundamentally Muskogean, even if structurally analytic and ultimately unintelligible to Muskogean speakers for larger constructions, unless they had considerable prior exposure to it.

Alternatively known as *anompa ĩla* ('other/different/strange talk'), *yama* ('yes, right, alright, indeed'), and *yoka anõpa* ('servant/slave talk'), MJ performed not only as a true pidgin in multilingual contexts with non-Muskogeans (as in intertribal gatherings, pantribal alliances, and intertribal and colonial trade), but also in bilingual contacts with distant peoples, including Algonquians, Siouans (such as the Osage), and eventually Europeans (as on long-distance travels, on diplomatic missions, in intertribal and interethnic marriages, and in the European employment of Indians). By the early 18th century, MJ moreover assumed meta-communicative functions of a sociolinguistic buffer against overly eager outsiders: its use helped confirm the native identity of its speakers, thus providing a safeguard against continuously threatening enslavement, while at the same time protecting their privacy against intrusions by missionaries, immigrant settlers, government officials, and anthropologists.

MJ's structure and functions raises questions about its origin. Because the linguistically and culturally fairly uniform Muskogeans had little reason to develop a pidgin, early analyses favored a colonial origin of MJ (Crawford, 1978). I have since proposed a pre-European origin for MJ on grounds of three interrelated arguments: its indigenous grammar and lexicon, its well-established use in diverse native interlingual contexts, and its geographic distribution closely overlapping with that of the linguistically diverse, but socioculturally quite uniform, paramount chiefdoms of the pre-Columbian moundbuilders known by archaeologists as the Mississippian Complex (Drechsel, 1996, 1997).

In classical propositional logic, all the operators are truth-functional. That is to say, the truth or falsity of a complex formula depends only on the truth or falsity of its simpler propositional constituents. Take the monadic operator $\sim$. This is interpreted to mean 'it is not the case that', and its meaning is defined by **Table 1**, called a truth table, in which 1 represents 'true' and 0 represents 'false'. This operator is truth-functional because the truth value of the complex proposition it forms is determined by the truth value of the proposition it starts with. If α has the value 1, then $\sim\alpha$ has 0. If α is 0, $\sim\alpha$ is 1. (I use standard operators for propositional logic: $\sim$ for negation, $\vee$ for (inclusive) disjunction, $\wedge$ for conjunction, $\supset$ for (material) implication and $\equiv$ for (material) equivalence.) Modal logic is concerned with understanding propositions about what **must** or about what **might** be the case, and it is not difficult to see how we might have two propositions alike in truth value, both true, say, where one is true and could not possibly be false and the other is true but might easily have been false. For instance it must be that $2+2=4$, but, although it is true that I am writing this entry, it might easily not have been. Modal logic extends the well-formed formulae (wff) of classical logic by the addition of a one-place sentential operator L (or $\Box$) interpreted as meaning 'it is necessary that'. Using this operator, an operator M (or $\Diamond$) meaning 'it is possible that' may be defined as $\sim L\sim$. The notation L and M for the necessity and possibility operators dates from Feys (1950) (for L) and Becker (1930) (for M). (For a history of notation, see Hughes and Cresswell, 1968: 347–349). The use of $\Box$ for the necessity operator is due to F. B. Fitch and first appears in Barcan (1946); the use of $\Diamond$ for M dates from Lewis and Langford (1932). In fact, any one of L or M can be taken as primitive and the other defined in terms of it. Another operator that may be defined in terms of L and M is the operator Q (or ∇), where $Q\alpha$ means that α is contingent, that is, neither necessary nor impossible. $Q\alpha$ may be defined as $\sim L\alpha \wedge M\alpha$. Many uses of *possible* in natural language suggest that what is possibly true is also possibly false, and those uses are better served by Q than by M.

The modern development of modal logic dates from 1912 when C. I. Lewis published the first of a series of articles and books (culminating in Lewis and Langford, 1932) in which he expressed dissatisfaction with the notion of material implication found in Whitehead and Russell's (1910) *Principia mathematica*. In the system of *Principia mathematica* – indeed in any standard system of propositional calculus (PC) – there are found the theorems:

(1) $p \supset (q \supset p)$

(2) $\sim p \supset (p \supset q)$

The sense of (1) is often expressed by saying that if a proposition is true, any proposition whatsoever implies it; the sense of (2) is often expressed by saying that if a proposition is false, it implies any proposition whatsoever. Lewis did not wish to reject these. He argued that they are "neither mysterious sayings, nor great discoveries, nor gross absurdities" (Lewis, 1912: 522), but merely reflect the truth-functional sense in which Whitehead and Russell were using the word *imply*. But he also maintained that there is a sense of *imply* in which when we say that *p implies q* we mean that '*q* follows from *p*' and that in this sense of *imply* it is not the case that every true proposition is implied by any proposition whatsoever or that every

In classical propositional logic, all the operators are truth-functional. That is to say, the truth or falsity of a complex formula depends only on the truth or falsity of its simpler propositional constituents. Take the monadic operator $\sim$. This is interpreted to mean 'it is not the case that', and its meaning is defined by Table 1, called a truth table, in which 1 represents 'true' and 0 represents 'false'. This operator is truth-functional because the truth value of the complex proposition it forms is determined by the truth value of the proposition it starts with. If α has the value 1, then $\sim\alpha$ has 0. If α is 0, $\sim\alpha$ is 1. (I use standard operators for propositional logic: $\sim$ for negation, $\vee$ for (inclusive) disjunction, $\wedge$ for conjunction, $\supset$ for (material) implication and $\equiv$ for (material) equivalence.) Modal logic is concerned with understanding propositions about what **must** or about what **might** be the case, and it is not difficult to see how we might have two propositions alike in truth value, both true, say, where one is true and could not possibly be false and the other is true but might easily have been false. For instance it must be that $2+2=4$, but, although it is true that I am writing this entry, it might easily not have been. Modal logic extends the well-formed formulae (wff) of classical logic by the addition of a one-place sentential operator L (or $\Box$) interpreted as meaning 'it is necessary that'. Using this operator, an operator M (or $\Diamond$) meaning 'it is possible that' may be defined as $\sim L\sim$. The notation L and M for the necessity and possibility operators dates from Feys (1950) (for L) and Becker (1930) (for M). (For a history of notation, see Hughes and Cresswell, 1968: 347–349). The use of $\Box$ for the necessity operator is due to F. B. Fitch and first appears in Barcan (1946); the use of $\Diamond$ for M dates from Lewis and Langford (1932). In fact, any one of L or M can be taken as primitive and the other defined in terms of it. Another operator that may be defined in terms of L and M is the operator Q (or ∇), where $Q\alpha$ means that α is contingent, that is, neither necessary nor impossible. $Q\alpha$ may be defined as $\sim L\alpha \wedge M\alpha$. Many uses of *possible* in natural language suggest that what is possibly true is also possibly false, and those uses are better served by Q than by M.

The modern development of modal logic dates from 1912 when C. I. Lewis published the first of a series of articles and books (culminating in Lewis and Langford, 1932) in which he expressed dissatisfaction with the notion of material implication found in Whitehead and Russell's (1910) *Principia mathematica*. In the system of *Principia mathematica* – indeed in any standard system of propositional calculus (PC) – there are found the theorems:

(1) $p \supset (q \supset p)$

(2) $\sim p \supset (p \supset q)$

The sense of (1) is often expressed by saying that if a proposition is true, any proposition whatsoever implies it; the sense of (2) is often expressed by saying that if a proposition is false, it implies any proposition whatsoever. Lewis did not wish to reject these. He argued that they are "neither mysterious sayings, nor great discoveries, nor gross absurdities" (Lewis, 1912: 522), but merely reflect the truth-functional sense in which Whitehead and Russell were using the word *imply*. But he also maintained that there is a sense of *imply* in which when we say that *p implies q* we mean that '*q* follows from *p*' and that in this sense of *imply* it is not the case that every true proposition is implied by any proposition whatsoever or that every

false proposition implies any proposition whatsoever. A brief account of the early history of modal logic is found in Hughes and Cresswell (1968: pt. 3, with Lewis's contributions documented in Chaps. 12–13).

Until the early 1960s, modal logics were discussed almost exclusively as axiomatic systems without access to a notion of validity of the kind used, for example, in the truth-table method for determining the validity of wff of the classical propositional calculus. The semantical breakthrough came by using the idea that a necessary proposition is one that is true in all possible worlds. But whether another world counts as possible may be held to be relative to the point we are at. So an interpretation for a modal system would consist of a set W of possible worlds and a relation R of accessibility between them – where the worlds accessible from a given world are often described as the worlds that world can see. For any wff α and world w, $L\alpha$ will be true at w iff α itself is true at every w' such that $w\mathrm{R}w'$. Put formally, a frame is a structure $\langle \mathrm{W},\mathrm{R}\rangle$ in which W can be any class at all, although it members are often called 'worlds' or 'indices,' and R is a relation between them. A model can then be based on that frame by adding a value assignment V. V assigns to each variable p a truth value in each world. If we read $\mathrm{V}(p,w)=1$ (0) as 'V assigns p the value true (false) in world w', then we may, for instance, define the truth table for $\sim$ so that $\mathrm{V}(\sim\alpha,w)=1$ if $\mathrm{V}(\alpha,w)=0$, and 0 otherwise, and we may define the disjunction operator $\vee$ so that $\mathrm{V}(\alpha \vee \beta,w)=1$ iff either $\mathrm{V}(\alpha,w)=1$ or $\mathrm{V}(\beta,w)=1$. $\mathrm{V}(L\alpha,w)=1$ iff $\mathrm{V}(\alpha,w')=1$ for every w' such that $w\mathrm{R}w'$. We define validity on a frame by saying that a wff α is valid on a frame $\langle \mathrm{W},\mathrm{R}\rangle$ iff, for every model $\langle \mathrm{W},\mathrm{R},\mathrm{V}\rangle$ based on $\langle \mathrm{W},\mathrm{R}\rangle$ and for every $w \in \mathrm{W}$, $\mathrm{V}(\alpha,w)=1$. The ideas that underlie this account of validity appeared in the late 1950s and early 1960s in the works of Kanger (1957), Bayart (1958), Kripke (1959, 1963), Montague (1960), and Hintikka (1961). Anticipations can be found in Wajsberg (1933), McKinsey (1945), Carnap (1946, 1947), Meredith (1956), Thomas (1962), and other works. An algebraic description of this notion of validity is found in Jónsson and Tarski (1951), although the connection with modal logic was not made in that article.

An axiomatic basis for a logical system consists of a selected set of wff, known as axioms, together with a set of transformation rules, licensing various operations on the axioms and on wff obtained from the axioms by previous applications of the transformation rules. The wff obtained from the axioms in this way, together with the axioms themselves, are known as the theorems of the system. The system of modal logic whose theorems are precisely the wff valid on every frame is known as the system K. This name, which has now become standard, was given to the system in Lemmon and Scott (1977) in honor of Saul Kripke, from whose work the way of defining validity for modal logic is mainly derived. The word 'frame' in this sense seems to have been first used in print in Segerberg (1968), but the word was suggested to him by Dana Scott. The axioms of K consist of all valid wff of PC together with the modal wff **K**:

$$L(p \supset q) \supset (Lp \supset Lq)$$

and it has the following three transformation rules:

- US (The Rule of Uniform Substitution): The result of uniformly replacing any variable or variables $p_1, \ldots, p_n$ in a theorem by any wff $\beta_1, \ldots, \beta_n$, respectively, is itself a theorem.
- MP (The Rule of Modus Ponens, sometimes also called the Rule of Detachment): If α and $\alpha \supset \beta$ are theorems, so is β.
- N (The Rule of Necessitation): If α is a theorem, so is $L\alpha$.

Other modal systems may be obtained by adding extra axioms to K. Each of these will be a proper extension of K (i.e., it will contain not only all the theorems of K but other theorems as well). Modal systems that contain K (including K, itself) together with US, MP, and N are commonly known as normal modal systems.

A wff valid on every frame is called K-valid, and the theorems of the system K are precisely those wff that are K-valid. It is important to be clear that this is a substantive fact and not something that is true by definition. To be a theorem of K is to be derivable from the axioms of K by the transformation rules of K; to be K-valid is to be valid on every frame, and the fact that a wff is a theorem of K iff it is K-valid is something we have to **prove**, not something we can assume. Similar remarks hold for extensions of K because different systems of modal logic can represent different ways of restricting necessity. It can then happen that whether a principle of modal logic holds or not can depend on the properties of the accessibility relation. We may have an axiomatic modal system defined without any reference to an account of validity and a definition of validity formulated without any reference to theoremhood in a system, and yet the theorems of that system are precisely the wff that are valid by that definition. To show that there is a match of this kind between a system and a validity definition, we have to prove two things: (1) that every theorem of the system is valid by that definition and (2) that every wff valid by that definition is a theorem of the system. If the first holds, we say that the system is sound, and if the second holds we say

that it is complete, in each case with respect to the validity-definition in question.

The wff $Lp \supset p$ is not K-valid because it is not valid on a frame in which there is a world that is not accessible from itself. (Put p false in this world, and true everywhere else.) We could, however, add it as an extra axiom to obtain a system stronger than K itself. The system obtained by adding $Lp \supset p$ as a single extra axiom to K is usually referred to as T, and it has had a long history in modal logic dating from Feys (1937). Feys's own name for the system is 't' (it was first called 'T' by Sobociński, 1953). Feys derived the system by dropping one of the axioms in a system devised by Gödel (1933), with whom the idea of axiomatizing modal logic by adding to PC originates. Sobociński showed that T is equivalent to the system M of von Wright (1951); for this reason 'M' was occasionally used as an alternative name for T. T is K + **T**.

T: $Lp \supset p$

Although **T** is not valid on every frame it **is** valid on all frames in which R is reflexive, that is, frames in which every world is accessible from itself – where $w\mathrm{R}w$ for every $w \in \mathrm{W}$. It can be proved that the system T is sound and complete with respect to such frames. In any system containing T, $L\alpha$ is equivalent to $\alpha \wedge \sim Q\alpha$, and so necessity may be defined in terms of contingency. Without T, this cannot usually be done. An examination of when necessity can be defined in terms of contingency in systems that do not contain T may be found in Cresswell (1988).

If we interpret L as expressing obligatoriness (moral necessity), we are unlikely to want to regard $Lp \supset p$ as valid because it will then mean that whatever ought to be the case is in fact the case. There is, however, a formula that, like $Lp \supset p$, is not a theorem of K but that, under the moral interpretation, it **is** plausible to regard as valid, and that is the wff $Lp \supset Mp$. If Lp means that it is obligatory that p, then Mp will mean that it is permissible that p (not obligatory that not-p), and so $Lp \supset Mp$ will mean that whatever is obligatory is at least permissible. This interpretation of L is known as a deontic interpretation, and for that reason $Lp \supset Mp$ is often called **D**, and the system obtained by adding it to K as an extra axiom is known as the system D; that is, D is defined as K + **D**.

D: $Lp \supset Mp$

D is sound and complete with respect to the class of frames in which R is serial – for every $w \in \mathrm{W}$, there is some w', perhaps w itself, as in T, but perhaps not, such that $w\mathrm{R}w'$.

In the early days of modal logic, disputes centered around the question of whether a given principle of modal logic was correct or not. Often these disputes involved formulae in which one modal operator occurs within the scope of another – formulae such as $Lp \supset LLp$. Sequences such as LL are known as iterated modalities, and it is tempting to consider the possibility that all iterated modalities might be equivalent to uniterated ones or to a small number of iterated ones. Consider the following:

(3) $Mp \equiv LMp$

(4) $Lp \equiv MLp$

(5) $Mp \equiv MMp$

(6) $Lp \equiv LLp$

None of these is a theorem even of T. Some of them can be derived from others. We can obtain (5) and (6) by adding $Lp \supset LLp$ to T; this system is known as the system S4. We can obtain all of (3)–(6) by adding $Mp \supset LMp$ to T; this system is known as the system S5. The names 'S4' and 'S5' derive from Lewis and Langford (1932: 501), in which systems deductively equivalent to these are the fourth and fifth in a series of modal systems. These systems too can be studied semantically. Suppose that R is required to be transitive; that is, suppose that, for any worlds w_1, w_2, and w_3, if $w_1\mathrm{R}w_2$ and $w_2\mathrm{R}w_3$ then $w_1\mathrm{R}w_3$. If so, then $Lp \supset LLp$ will be valid, but if nontransitive frames are permitted it need not be. S4 is sound and complete with respect to all reflexive and transitive frames. Suppose that in addition R is symmetrical, that is, if $w\mathrm{R}w'$ then $w'\mathrm{R}w$. S5 is sound and complete with respect to all reflexive, transitive, and symmetrical frames.

Not all normal modal logics are so well-behaved, however. There exist systems that can be proved to be incomplete in the sense that there is **no** class of frames such that their theorems are precisely the wff that are valid on every frame in the class. One simple example is the system KH = K + **H**.

H: $L(Lp \equiv p) \supset Lp$

Every frame for H also validates $Lp \supset LLp$, but $Lp \supset LLp$ is not a theorem of KH. The incompleteness of this system is proved in Boolos and Sambin (1985). A simplified proof appears in Hughes and Cresswell (1996: Chap. 9). Much current research in propositional modal logic is devoted to the systematic study of large families of logics to examine the conditions under which they have, or lack, properties such as these.

Modal logic can be given a temporal interpretation. The propositional logic of linear time in which L means 'it is and always will be that ...' is called S4.3; it is S4 together with **D1**.

D1: $L(Lp \supset q) \vee L(Lq \supset p)$

The logic of discrete time, in which each moment has a unique successor, S4.3.1, is S4.3 + **N1**.

N1: $L(L(p \supset Lp) \supset p) \supset (MLp \supset Lp)$

This logic has a venerable history. In 1957, Arthur Prior conjectured that S4 was the logic of time with this structure, but later authors proved it to be S4.3.1. Prior's name for this was D (for Diodorus Cronos, not to be confused with D for the deontic system). The history is told in Prior (1967: Chap. 2). Another logic with a philosophical and mathematical interest is one variously called KW or G. It is K together with **W**.

W: $L(Lp \supset p) \supset Lp$

One of its interpretations is that it expresses the logic of provability – with L meaning, 'it is provable that'. From a purely modal point of view, it is sound and complete with respect to the class of all finite frames in which R is transitive and asymmetrical. The name W is from Segerberg (1971: 84); it is called G in Boolos (1979). For a more recent survey of the history of provability logic, see Boolos and Sambin (1990). The system dates at least from Löb (1966).

An important modal notion is that of entailment. By this we understand the converse of the relation of following logically from (when this is understood as a relation between propositions, not wff); that is, to say that a proposition, p, entails a proposition, q, is simply an alternative way of saying that q follows logically from p or that the inference from p to q is logically valid. In modal logic, we can say that p entails q iff $L(p \supset q)$. But then we are faced with the following valid wff.

(7) $L((p \wedge \sim p) \supset q)$

(8) $L((q \supset (p \vee \sim p))$

With this interpretation, (7) means that any proposition of the form $(p \wedge \sim p)$ entails any proposition whatever, and (8) means that any proposition whatever entails any proposition of the form $(p \vee \sim p)$. Although this may seem strange, those who wish to reject either (7) or (8) have to face the following argument. The following principles seem intuitively to be valid:

1. Any conjunction entails each of its conjuncts.
2. Any proposition, p, entails $(p \vee q)$, no matter what q may be.
3. The premises $(p \vee q)$ and $\sim p$ together entail the conclusion q (the principle of the disjunctive syllogism).
4. Whenever p entails q and q entails r, then p entails r (the principle of the transitivity of entailment).

Table 2 Derivation of propostions using the four principles

Principle	Proposition
	(i) $p \wedge \sim p$
From (i), by A	(ii) p
From (ii), by B	(iii) $p \vee q$
From (i), by A	(iv) $\sim p$
From (iii) and (iv), by C	(v) q
So by **D**, $(p \wedge \sim p)$ entails q	

Lewis showed long ago (Lewis and Langford, 1932: 250–251) that by using these principles we can always derive any arbitrary proposition, q, from any proposition of the form $(p \wedge \sim p)$, as shown in Table 2. This derivation shows that the price that has to be paid for denying that $(p \wedge \sim p)$ entails q is the abandonment of at least one of the principles 1–4. The most fully developed formal response to these paradoxes consists of abandoning principle 3, the principle of disjunctive syllogism. Logics that do this are called relevance logics. A survey of relevance logic is found in Dunn (1986) and Mares and Meyer (2001).

First-order predicate logic can also be extended by the addition of modal operators. (For more details of modal predicate logic see Hughes and Cresswell, 1996: pt. 3; Garson, 1984.) The most interesting consequences of such extensions are those that affect mixed principles, principles that relate quantifiers and modal operators and that cannot be stated at the level of modal propositional logic or nonmodal predicate logic. Thus, (9) is valid, but (10) is not.

(9) $\exists x L\alpha \supset L\exists x\alpha$

(10) $L\exists x\alpha \supset \exists x L\alpha$

(Even if a game must have a winner there need be no one who must win.) In some cases the principles of the extended system will depend on the propositional logic on which it is based. An example is a formula studied by Ruth Barcan Marcus, who first considered combining modal logic with first-order predicate logic and introduced the formula in Barcan (1946). The Barcan formula (BF) is:

$\forall x L\alpha \supset L\forall x\alpha$

which is provable in some modal systems but not in others. If both directions are assumed, so that we have $\forall x L\alpha \equiv L\forall x\alpha$, then this formula expresses the principle that the domain of individuals is held constant over all possible worlds. A temporal version of the Barcan formula might make its interpretation clearer. Let us assume that everyone now in existence will die before 2154. Then, if L means 'it will always

be the case that' and α is the wff 'x dies before 2154', then $\forall x L\alpha$ is true. But it is not at all likely that it will always be the case that everyone will die before 2154 because people who do not now exist may well live beyond then, and so $L\forall x\alpha$ will be false. This assumes that a quantifier only ranges over the individuals that exist at the time or in the world at which the wff is being evaluated, but indicates why BF has been a matter of controversy.

It is possible to have complete predicate logics whose predicate extensions are incomplete. One such is S4.2, which is S4 + **G1**.

G1: $MLp \supset LMp$

S4.2 is characterized by frames that are reflexive, transitive, and convergent, in the sense that, if a world w_1 can see two worlds w_2 and w_3 then there is a world w_4 that both w_2 and w_3 can see. But the predicate extension of S4.2 + BF is not characterized by any class of frames. Perhaps more interesting is the case of the systems S4.3.1 and KW (or G) previously mentioned, the logics of discrete time and of provability. It is established in Cresswell (1997) that the predicate logic characterized by all frames for these systems is not recursively axiomatizable because they, together with a whole family of systems containing N1 and $Lp \supset LLp$, when combined with first-order logic, enable the expression of second-order arithmetic.

When identity is added, even more questions arise. The usual axioms for identity easily allow the derivation of LI:

$(x = y) \supset L(x = y)$

but should we really say that all identities are necessary? Take:

(11) the composer of 'Threnody for Mrs S' = the composer of 'Salm'

An important feature of (11) is that it uses the phrases *the composer of 'Threnody for Mrs S'* and *the composer of 'Salm'*. Such phrases are often called definite descriptions, and they pose problems even in nonmodal predicate logic. One of the first to see this was Bertrand Russell, whose celebrated example was

(12) the present king of France is bald

Because there is no present king of France, it would seem that (12) is false. But then it would seem that (13) is true.

(13) the present king of France is not bald

But (13) does not seem true either, for the same reason as (12). Even worse is sentence (14).

(14) the present king of France does not exist

Russell claimed that the phrase *the present king of France* does not function like a name at all, and his account of the matter can help with (11). If we follow Russell, (11) makes five claims:

1. At least one person composed 'Threnody for Mrs S.'
2. At most one person composed 'Threnody for Mrs S.'
3. At least one person composed 'Salm.'
4. At most one person composed 'Salm.'
5. $\forall x \forall y$(x composed 'Threnody for Mrs S' $\wedge$ y composed 'Salm') $\supset x = y$).

Look carefully at claim 5. This claim is true but not necessarily true, so putting L in front of it gives us a false sentence. But LI does not license us to put L in front of claim 5. What LI does allow is for us to move from claim 5 to claim 6.

6. $\forall x \forall y$(x composed 'Threnody for Mrs S' $\wedge$ y composed 'Salm') $\supset L(x = y)$).

And it is less clear that claim 6 is at all objectionable.

Suppose, nevertheless, that we still wish to abandon LI. To falsify LI, we let the values of the variables be strings of objects that may coincide in some worlds but not in others. In the present example, letting x mean 'The composer of "Threnody for Mrs S"' would mean requiring its value in a world w be whoever in w composed 'Threnody for Mrs S,' while y could stand for whoever composed 'Salm' in w. But there is a problem. Allowing all such strings would make the wff (10) valid, and it was remarked that (10) could be false in a game in which it is necessary that some player will win, although there is no individual player who is bound to win. There is, however, one way in which we could make (10) sound plausible. Consider, for example, the expression *the governor-general of New Zealand*, as it may occur in a constitutional context. The law may specify that at a certain point the signature of the governor-general is required before an act of parliament becomes law; yet on one occasion the governor-general may be Michael Hardie-Boys and on another it may be Sylvia Cartwright. Thus, the phrase *the governor-general of New Zealand* does not designate any particular individual (as an assemblage of flesh and blood); yet we can in a sense think of it as standing for a single object, contrasted with *the prime minister* and so forth.

Such objects are often called intensional objects or individual concepts. In a logic in which the individual variables range over all intensional objects, (10) would be valid because, if it must be the case that there is someone who must sign acts into law, then

although no individual person must be that someone, yet there is someone (viz. the governor-general) whose signature is required. An adequate semantics for the contingent identity systems that do not validate (10) would therefore have to place restrictions on allowable strings of objects and neither require that only strings consisting of the same member of D in each world should count as objects—for that would validate LI – nor that any string whatever of members of D should count as an object – for that would validate (10).

All the systems of modal logic considered so far have assumed a single necessity operator, with its possibility dual. An important class of systems with more than one is the class of tense logics. (For a survey see Prior, 1967.) A tense logic has two operators, L_1 and L_2, where L_1 means 'it always will be the case that' and L_2 means 'it always has been the case that'. In frames for a tense logic, the associated relations R_1 and R_2 are so related that one is the converse of the other, that is, wR_1w' iff $w'R_2w$. Another way of introducing families of modal operators is suggested by a possible interpretation of modal logic in computer science. In this interpretation, the worlds are states in the running of a program. If π is a computer program, then $[\pi]\alpha$ means that, after program π has been run, α will be true. If w is any world, then $wR_\pi w'$ means that state w' results from the running of program π. This interpretation of modal logic is called dynamic logic. What gives dynamic logic its interest is the possibility of combining simple programs to get more complex ones. Thus, if π_1 and π_2 are two programs, then the expression $\pi_1;\pi_2$ refers to the program 'first do π_1 and then do π_2', and $[\pi_1;\pi_2]\alpha$ means that α will be true if this is done. The relation corresponding to $[\pi_1;\pi_2]$ may be defined to hold between w and w' iff $\exists u(wR_{\pi 1}u \wedge uR_{\pi 2}w')$. Other computing operations can generate similar modal operators, with appropriate conditions on their accessibility relations (see Goldblatt, 1987: Chap. 10). It is also possible to develop dynamic predicate logic. For an introductory survey, see Goldblatt (1987: pt. 3).

The most general kind of possible-worlds semantics for propositional operators is based on that idea of the truth set of a formula. In any model, we can define $|\alpha|$ as $\{w \in W: V(\alpha,w) = 1\}$. In evaluating $L\alpha$ in a world w, all the input that we require is to know which set of worlds forms the truth set of α. Whatever L means, what it has to do is to declare $L\alpha$ true at w for some truth sets and false for others. So the meaning of L must specify which sets of worlds form acceptable truth sets in world w. These sets of worlds are called the neighborhoods of w, and a neighborhood frame for a language of modal propositional logic is a pair $\langle W,R\rangle$ in which W is a set (of worlds) and R is a neighborhood relation. (For some remarks on the history of neighborhood semantics, see Segerberg, 1971: 72.) A neighborhood relation is a relation between a world w and a subset A of W, and A is a neighborhood of w iff wRA. We then say that $V(L\alpha,w) = 1$ iff $wR|\alpha|A$. A frame of the kind assumed earlier, in which R is a relation between worlds, is often called a relational frame, and it is not difficult to see that every relational frame is a special case of a neighborhood frame. To be precise, a relational frame is a neighborhood frame in which for every $w \in W$ there is a set B of those and only those worlds that are accessible to w (i.e., B is the set of worlds w can 'see') and wRA iff $B \subseteq A$. What this means is that α's truth set is a neighborhood of w iff it contains all the worlds accessible from W, which is of course precisely what the truth of $L\alpha$ in a relational frame amounts to.

Neighborhood semantics can be devised for systems with operators taking more than one argument. A philosophically important example here is the logic of counterfactuals as developed in the late 1960s and early 1970s. We present here a version of the semantics found in Lewis (1973), but the same idea is also found in Stalnaker (1968) and Åqvist (1973). Counterfactual logic is based on a dyadic operator $\Box\!\!\rightarrow$, where $\alpha \Box\!\!\rightarrow \beta$ means that 'if α were to be the case then β would be the case'. Lewis's idea is that, given a possible world w, some worlds are closer to w than others. If we write $w' <_w w''$ to mean that 'w' is closer to w than w'' is', then the semantics for $\Box\!\!\rightarrow$ will be that $\alpha \Box\!\!\rightarrow \beta$ is true in w iff either α is not true at any world or there is a world w' at which α and β are both true that is closer to w than any world w'' at which α is true but β is not. A counterfactual frame can be described as a neighborhood frame in the following way. Because $\Box\!\!\rightarrow$ is dyadic, its neighborhood relation R will relate worlds to pairs $\langle A,B\rangle$ where $A \subseteq W$ and $B \subseteq W$. The standard rule for a dyadic operator δ using an associated neighborhood relation R is (15).

(15) $V(\delta\alpha\beta,w) = 1$ iff $wR\langle|\alpha|, |\beta|\rangle$

A frame $\langle W,R\rangle$ will be a counterfactual frame iff it is based on a nearness relation $<$ in such a way that $wR\langle A,B\rangle$ iff either (16) or (17).

(16) $A = \varnothing$

(17) There is some w' such that $w' \in A \cap B$ and for every w'', if $w'' \in A \cap -B$ then $w' <_w w''$

Which counterfactual logic we get will depend on what kind of conditions we put on $<$. For instance, under the plausible assumption that the closest world to w is w itself, we get a frame that validates the wff in (18).

(18) $p \supset ((p \Box\!\!\rightarrow q) \equiv q)$

By contrast, on any plausible account of nearness, many wff that are valid for $\supset$ fail for $\Box\!\!\rightarrow$. For instance in standard systems of counterfactual logic, neither (19) nor (20) is valid.

(19) $((p \Box\!\!\rightarrow q) \wedge (q \Box\!\!\rightarrow r)) \supset (p \Box\!\!\rightarrow r)$

(20) $(p \Box\!\!\rightarrow q) \supset (\sim q \Box\!\!\rightarrow \sim p)$

Questions such as these bring us to the boundary between modal logic, metaphysics, and semantics and remind us of the rich potential that the theory of possible worlds has for illuminating such issues. The possible-worlds semantics can be generalized to deal with any operators whose meanings are operations on propositions as sets of possible worlds and form a congenial tool for those who think that the meaning of a sentence is its truth conditions and that these be taken literally as a set of possible worlds – the worlds in which the sentence is true.

Further information on modal logic, including more detailed bibliographical references, may be found in a number of works. See, for instance, Blackburn *et al.* (2001), Bull and Segerberg (1984), Chargrov and Zaharyaschev (1997), Chellas (1980), and Hughes and Cresswell (1996).

Modality Issues in Signed and Spoken Language

R P Meier, University of Texas at Austin, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

The modality of a language is the means by which that language is produced and perceived. Linguists long believed that human language was bound to a particular modality; language was necessarily spoken and heard (e.g., Hockett, 1960). Reading and writing were not overlooked, but these visual representations are largely derivative of a primary spoken language. Research since 1960 has shown that there are two modalities in which naturally evolved human languages are expressed: not only the oral–aural modality of spoken languages, but also the visual–gestural modality of signed languages. There may even be a third possibility: specifically the tactile–gestural modality that is used in deaf–blind signing (see Quinto-Pozos, 2002). However, we know of no independent languages that have emerged within the tactile–gestural modality.

Signed and spoken languages are encoded using different articulators, and decoded using different sensory-perceptual systems. Beyond such obvious facts as the irrelevance of voicing to signed languages and of handshape to spoken languages, there are interesting differences between the two language modalities; see **Table 1** and **Table 2** (adapted from Meier, 2002b). For example, in speech, the oral articulators are largely hidden from view; thus the failure of lip reading as a means of understanding speech. Although hearing addressees are not blind to the visual configuration of the oral articulators (as demonstrated by the McGurk effect), addressees must perceive the acoustic consequences of oral articulation if they are to understand the speaker. The relationship between auditory percept and articulator movement is exceedingly complex, a fact that

Table 1 Some properties of the articulators in sign and speech

Sign	*Speech*
Light source external to signer	Sound source internal to speaker
Manual articulation not coupled (or loosely coupled) to respiration	Oral articulation tightly coupled to respiration
Manual articulators move in a transparent space	Oral articulators largely hidden
Manual articulators relatively massive	Oral articulators relatively small
Manual articulators paired	Oral articulators not paired
No predominant oscillator associated with sign syllables	Mandible is predominant oscillator associated with speech syllables

Modality Issues in Signed and Spoken Language

R P Meier, University of Texas at Austin, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

The modality of a language is the means by which that language is produced and perceived. Linguists long believed that human language was bound to a particular modality; language was necessarily spoken and heard (e.g., Hockett, 1960). Reading and writing were not overlooked, but these visual representations are largely derivative of a primary spoken language. Research since 1960 has shown that there are two modalities in which naturally evolved human languages are expressed: not only the oral–aural modality of spoken languages, but also the visual–gestural modality of signed languages. There may even be a third possibility: specifically the tactile–gestural modality that is used in deaf–blind signing (see Quinto-Pozos, 2002). However, we know of no independent languages that have emerged within the tactile–gestural modality.

Signed and spoken languages are encoded using different articulators, and decoded using different sensory-perceptual systems. Beyond such obvious facts as the irrelevance of voicing to signed languages and of handshape to spoken languages, there are interesting differences between the two language modalities; see Table 1 and Table 2 (adapted from Meier, 2002b). For example, in speech, the oral articulators are largely hidden from view; thus the failure of lip reading as a means of understanding speech. Although hearing addressees are not blind to the visual configuration of the oral articulators (as demonstrated by the McGurk effect), addressees must perceive the acoustic consequences of oral articulation if they are to understand the speaker. The relationship between auditory percept and articulator movement is exceedingly complex, a fact that

Table 1 Some properties of the articulators in sign and speech

Sign	*Speech*
Light source external to signer	Sound source internal to speaker
Manual articulation not coupled (or loosely coupled) to respiration	Oral articulation tightly coupled to respiration
Manual articulators move in a transparent space	Oral articulators largely hidden
Manual articulators relatively massive	Oral articulators relatively small
Manual articulators paired	Oral articulators not paired
No predominant oscillator associated with sign syllables	Mandible is predominant oscillator associated with speech syllables

Table 2 Some properties of the sensory and perceptual systems subserving sign and speech

Sign	*Speech*
Signer must be in view of addressee	Speaker need not be in view of addressee
High bandwidth of vision	Lower bandwidth of audition
High spatial resolution of vision; lower temporal resolution than audition	High temporal resolution of audition; lower spatial resolution than vision
Articulatory gestures as the object of perception	Acoustic events as the object of perception

contributes to the intractability of the so-called invariance problem in speech perception.

Because the manual articulators move within the transparent space in front of the signer (the 'signing space'), the postures of the hands and their movements can be directly observed. If he or she chooses, the addressee can attend to the movements and postures of those articulators (although any addressee normally attends to the signer's message, not its articulation). The addressee in a spoken conversation cannot attend directly to the position of the vocal cords, or to movements of the tongue body, or to the lowering or raising of the velum.

Do such modality differences have important effects on the structure, acquisition, and processing of signed versus spoken languages? The research to date inescapably leads to the conclusion that there are many noneffects of modality upon linguistic structure and processing. In crucial ways, signed and spoken languages are structured similarly. Evidence for particular modality effects is more scattered. The subsequent paragraphs examine: 1) Noneffects of modality, 2) Methodological issues that make the identification of modality effects difficult, and 3) Evidence for modality effects.

Noneffects of Modality

Spoken and signed languages share many properties. In signed and spoken languages, a lexical item is a form-meaning pair that is conventional within a particular linguistic community (see Saussure, 1916/1959). Just as the English word *tree* and the Spanish word *arbol* share the same meaning but have very different forms, the signs for 'tree' in American Sign Language (ASL), Danish Sign Language, and Chinese Sign Language are quite distinct in form, although – as it happens – each of these signs is in its own way quite iconic (Klima and Bellugi, 1979). In signed and spoken languages, meaningful units (words or signs) are built in rule-governed ways from meaningless units of sound or gesture (Brentari, 1998; Stokoe *et al.*, 1965). Slips of the hand show that these sublexical units are not merely convenient descriptive devices for the linguist; they are instead integral to a signer's planning of utterances (for ASL, Klima and Bellugi, 1979; for German Sign Language, Hohenberger *et al.*, 2002). These meaningless units of handshape, movement, and place of articulation form the lines of cleavage along which signs break apart when signers err, just as phonemic segments may be switched, anticipated, or perseverated in slips of the tongue. Thus, signed and spoken language show what Hockett (1960) called duality of patterning.

Signed and spoken languages have open-ended vocabularies; they add new lexical items by means of derivational morphology (e.g., Supalla and Newport, 1978), compounding (Klima and Bellugi, 1979), and borrowing (Battison, 1978; Padden, 1998). In signed languages, as in spoken languages, syntactic rules constrain the concatenation of signs within sentences (Liddell, 1980). Signed languages display the same parts of speech as spoken languages. They use word order and verb agreement to mark subject and object. Evidence of subordinate clauses in ASL and other signed languages means that recursion is a property of signed and spoken languages alike (e.g., Padden, 1983).

The developmental milestones of language occur on roughly the same schedule in signing and speaking children (Newport and Meier, 1985; Meier, 1991). In general, adult processing of signed and spoken languages has proven to be fundamentally similar, although there have been discussions about the extent of right hemisphere involvement in the processing of sign and about whether sign shares with speech the property of being categorically perceived; see Emmorey (2002) for a review.

Noneffects of modality can be important for our understanding of human language. The findings reviewed here show that many crucial properties of human language are not products of a particular modality of transmission; instead those properties are common to signed and spoken languages. The striking similarities in linguistic structure, in child language development, and in adult processing between signed and spoken languages demonstrate that, with respect to the modality of language, the human language capacity is highly plastic.

Problems in Identifying Modality Effects

Given that signed and spoken languages share so many fundamental properties, are there nonetheless interesting differences between signed and spoken languages? For various reasons, it is not easy to

identify effects of the particular modality in which a language is expressed or perceived. First, there are problems of sample size: there are many fewer signed languages than spoken languages. The much larger set of spoken languages gives those languages more opportunity to express linguistically unusual properties. Even within the relatively small set of signed languages, most attention has focused on just one language, ASL. Although recent years have brought important work on other signed languages, much of that work has examined European signed languages, some of which have historical links to ASL through French Sign Language.

A second problem lies in the fact that most, if not all, signed languages are relatively young languages. Young languages – whether signed or spoken – may not fully represent the space of linguistic possibilities that are available within a given language modality; thus spoken Creole languages may be relatively uniform in their structure (Bickerton, 1984). Note that, the youth of signed languages is not an inherent property of the modality, but is instead an artifact of the demography of the deaf community and of attitudes toward deaf education. Interestingly, the unusual demographics of signing communities may serve to keep signed languages young. For deaf children, parent-to-child transmission of language is the exception, not the rule. Few deaf children are the offspring of native signing parents. Frequent interruption of the generation-to-generation transmission of language may mean that in signed languages, more than in spoken languages, children can shape languages that conform to their own biases. Languages that closely fit children's biases may represent only a subset of the kinds of languages that are learnable within a given modality.

Examples of Possible Modality Effects

The Resources of the Visual–Gestural Modality

The visual–gestural modality makes a three-dimensional space available to signed languages. It also enables many conceptually important lexical items to have some iconic basis. Iconic lexical items are possible in both language modalities: in spoken languages, onomatopoetic words such as *cock-a-doodle-doo* or Spanish *quiquiriqui* are sound images. Such words are not *ad hoc* creations; they are instead conventional members of the lexicon of a specific language. The resources of the visual–gestural modality appear to allow more frequent iconicity in sign language lexicons. For example, the ASL sign HOUSE seems to sketch a two-storey house with a peaked roof, as shown in Figure 1. However iconic,

Figure 1 The ASL sign HOUSE. Drawing by Frank A. Paul, copyright RPM.

this sign is a conventional member of the ASL lexicon. What allows frequent iconicity in the visual–gestural modality? Contributors may include the fact that the two hands can move in tandem through the transparent sign space to sketch the shape of objects. The visible movement of hands through that sign space can also be used to represent the movement of objects in the world (including movement of the hand itself). In contrast, the oral–aural modality of spoken languages seems to have a limited capacity for iconic representation; in most instances, arbitrary words are the only available option (cf. Goldin-Meadow and McNeill, 1999).

The incidence of iconicity in signed languages – and the less-frequent occurrence of iconic spoken words – allows us to reassess the role of arbitrariness in language. The human language capacity does not demand arbitrary words or signs. Instead, all languages must allow arbitrary signs. Absent arbitrariness, languages could not readily express concepts that are not imageable. So, in ASL, signs such as BLACK, HOME, CURIOUS, and GIRL are fundamentally arbitrary; as shown in Figure 2, an inward rotation of the forearm in the sign BLACK causes the tip of the index finger to brush the forehead. This sign has no obvious motivation.

Iconicity appears to have few consequences for the grammar of signed languages: for example, morphological processes are not blocked by the iconicity of the lexical items to which those processes apply (e.g.,

The subscripts indicate locations associated with the signer (1), the addressee (2), and a nonaddressed participant on the signer's left (3j). Drawings by Frank A. Paul, copyright RPM.

Klima and Bellugi, 1979). In many instances, the iconic properties of signs have been obscured by historical change (Frishberg, 1975). Iconicity does not appear to be an important determinant of the overall timecourse of language acquisition, of the kinds of errors children make, or of which signs children learn first (see Newport and Meier, 1985, for a review). But the iconic potential of the visual–gestural modality does appear to be an important contributor to the rapid emergence of signed languages, in particular the home sign systems that are invented by deaf children of hearing, nonsigning parents (Goldin-Meadow, 2003). A deaf child can reasonably expect that iconic gestures will be understood by nonsigning parents.

The resources of the visual gestural modality give signed languages access to a three-dimensional space not just for the movement of the hands, but also as a source of locations that signs may indicate. To refer to people, objects, and locations that are not present in the immediate environment of a signed conversation, the signer may associate that referent with an empty location in space. Later in the conversation, signer and addressee alike can continue to use that location when they wish to refer anaphorically to that same referent (Bellugi and Klima, 1982). Many transitive verbs can move between locations in space (whether the real-world locations of referents or empty locations established in the sign space) to indicate the referents of their subjects and objects; see Figure 3. The ready availability of the sign space for referential purposes appears to have important consequences for the grammar of deixis (Meier, 1990; McBurney, 2002), verb agreement (Meier, 2002a; Liddell, 2003), and anaphora (Lillo-Martin, 1990) in signed languages. The availability of this sign space may also be one factor accounting for the substantial uniformity in how these grammatical phenomena are manifest in different signed languages.

The use of space is not an inevitable product of the visual-gestural modality, although it appears characteristic of all naturally evolved signed languages examined to date (with the apparent exception of Abu-Shara Bedouin Sign Language, a very newly emerged sign language described by Aronoff *et al.*, forthcoming). Sign systems that do not use space are imaginable: for example, artificial sign systems such as Signing Exact English (SEE 2) are organized like English and make little use of the sign space for referential purposes. However, deaf children who are exposed only to SEE 2 adapt that system so that space is used in ways akin to the uses of space in naturally evolved sign languages (Supalla, 1991).

Rate of Signing

Perhaps because the sign articulators are massive and must often execute long movement excursions, signing rate (i.e., the rate at which signs are produced) appears relatively slow compared to the rate at which English words are produced. But, paradoxically, the

rate at which propositions are transmitted is the same in ASL and English (Bellugi and Fischer, 1972; Klima and Bellugi, 1979). How can this happen?

Bellugi and Fischer resolved this paradox – a slow signing rate that has no effect on the rate at which propositions are transmitted – by looking to the typological organization of signed languages. They argued that simultaneity in ASL morphology and in syntactic marking allows efficient transmission of propositions. In this view, natural signed languages largely avoid sequential morphological structure; that is, they avoid affixation. In Bellugi and Fischer's data, utterances from an artificial sign system that has English-like morphological structure (i.e., affixation) were slow to be produced and, for that reason, such systems may be disfavored by the Deaf community. Instead, natural sign languages rely largely on morphological processes that are nonconcatenative: for example, contrasting patterns of repetition, doubling of the hands in one-handed signs, and changes in movement direction or palm orientation that reflect the spatial locations linked to a verb's arguments. Sign languages also seem to favor the use of facial expression as adverbial markers and as markers of grammatical structure: e.g., facial expressions marking different sentence types. These nonmanual markers may be articulated simultaneously with manual signs.

Nonconcatenative morphology is certainly possible in spoken languages: e.g., the root and pattern morphology of Semitic languages, ablaut in Germanic languages, and tonal morphology in many African languages. However, signed and spoken languages seem to differ in their preferred type of morphological organization, with spoken languages generally opting for sequential structures of stems and affixes. In contrast, such morphology is sparse in signed languages; although compounding (which is of course sequential) is common in signed languages, nonconcatenative inflectional and derivational morphology is, with a small set of possible exceptions, the rule (Aronoff *et al.*, 2005).

Conclusions

Signed and spoken languages share many fundamental properties of linguistic organization. They may differ in subtle ways, too: for example, signed and spoken languages may differ in their predominant typological organization. It has also been hypothesized that signed and spoken languages might differ such that signed languages are relatively more uniform in their grammatical properties, whereas spoken languages are more diverse (Newport and Supalla, 2000). Much further research will be necessary to confirm the extent to which these hypothesized differences are true. Explaining these differences will also require substantial work. For example, the relative uniformity of signed languages in contrast to the diversity of spoken languages might arise from the differing properties of the two language modalities. But it might also be a consequence of the interesting history and demography of signing communities – specifically the fact that signed languages are relatively young languages (sometimes exceedingly young, as is Nicaraguan Sign Language (Senghas and Coppola, 2001)). The demography of signing communities might mean that the learning biases of children – and not necessarily the constraints of the visual–gestural modality – may have a crucial role in structuring signed languages. We have every reason to think that children's biases are much the same from community to community and generation to generation. Further research is needed to examine just how varied signed languages are, to detail the role that children play in elaborating signed languages, and to uncover the precise role that modality factors might have in shaping signed languages.

Modern Linguistics: 1800 to the Present Day

R Harris, Oxford, UK

Introduction

It is during the course of the 19th century that we first find linguists self-consciously making statements about the history of their own discipline. The very fact that they do so is part of the *prima facie* evidence for the existence of that discipline (as indeed it was intended to be). For, it need hardly be said, their main concern was not so much to establish what had happened in the past as to establish the contemporary autonomy of their own branch of inquiry. For this purpose they usually adopted a familiar "torch of learning" model, in which knowledge is passed on from one age to the next. As successive generations fan the sacred Flame with their own contribution, it burns ever brighter. The current torch-holder often turns out to be the scholar telling the story, or a close colleague.

This pattern of historical self-justification has been repeated more or less without interruption in linguistics from 1800 down to the present day, beginning with the Comparative Philologists and continuing with the Neogrammarians. A classic case from the early 20th century is the introductory chapter in F. de Saussure's *Cours de linguistique générale* (1916), which itself recruits the Comparative Philologists and the Neogrammarians as honorable predecessors. Another is chapters 1–4 of *Language: its nature, development and origin* (Jespersen, 1922). A third is chapter 1 of *Language* (Bloomfield, 1933). A fourth and even more blatant example (if that were possible) is *Linguistics* (Fries, 1966), which leads up to what Fries calls triumphantly "the breakthrough" of American structural linguistics and the arrival of transformational-generative grammar. Endemic to this self-justificatory pattern is the notion that one's predecessors, although great scholars, never quite got it right (or even, occasionally, got it wrong, thus all but extinguishing the Flame).

Underlying most of these self-justificatory historical accounts lies a concern to show that linguistics is – or at last has now, i.e., in the author's own generation, become – a 'science.' This anxiety is bound up with the whole question of the academic prestige of 'the sciences' as developed in 19th- and 20th-century universities in Europe, and the diminishing prestige of 'the arts.' 'Science' was from the beginning a watchword or slogan that modern linguistics appropriated as its own, thus implicitly distinguishing the subject from all 'pre-scientific' studies of language and languages. It is emphatically reaffirmed in the glossary to the first edition of this encyclopedia, which contains the blunt propagandist equation "linguistic science = linguistics" (Asher, 1994).

The brief account that follows describes the main phases usually identified in this self-serving tradition of historiography. It makes no attempt to list all the individual 'schools' and 'movements' that have contributed to modern linguistics, let alone all the eminent scholars. Nor does it cover 'applied' linguistics in such diverse areas as language acquisition, language pathology, language planning, language teaching, and psycholinguistics.

Comparative Philology

Modern linguistics is usually portrayed as arising out of a preceding inquiry called Comparative Philology or Comparative Grammar. The Comparativists were already anxious to distinguish themselves from an earlier scholarly tradition that they often referred to as Classical Philology. Adopting a "torch of learning" model requires an identification of some person or persons who first lit the torch. That role was retrospectively thrust, by the Comparativists and their successors, upon Sir William Jones (1746–1794).

According to later scholars seeking to validate their version of the history of linguistics, the stimulus that Jones provided to 19th-century developments was 'immense' (Robins, 1994). But this overenthusiastic claim is based mainly on the endless quotation of one paragraph from a single lecture that Jones gave in India to the Asiatic Society in 1786. There he proposed that Sanskrit, Greek, and Latin were languages that might be derived from "some common source, which, perhaps, no longer exists." He also suggested in the same paragraph that Gothic, Celtic, and Old Persian might have belonged to the same family.

On this flimsy evidence, Jones could hardly have anticipated that later generations would hail him as a 'founder' of Comparative Philology, much less as 'the first modern linguist.' Jones was a newly arrived British judge sent out from London to administer colonial justice in India. What he saw was the practical advantage of having at his disposal a digest of Hindu and Islamic law. For this purpose, a knowledge of Sanskrit was essential, and he applied himself to it. The irony is that Jones himself had no great regard for philological studies as such. As far as he was concerned, languages were "mere instruments of

real learning." They were not objects of study in their own right.

But that, precisely, was the central notion of the Comparativists. In their view, languages were in themselves organic growths, developing in accordance with their own organic nature, and therefore qualifying as raw 'materials' for a modern science of language. On this basis, as F. M. Müller (1823–1900), first professor of Comparative Philology at Oxford, insisted, it was possible to envisage the study of languages as comparable to such natural sciences as biology and astronomy. But no such project was further from the mind of Jones.

The scholars who, in practice, set up Comparative Philology as an academic discipline were J. Grimm (1785–1863), R. Rask (1787–1832), and F. Bopp (1791–1867). Their work had as its focus the comparative study of the Indo-European languages. They were not engaged in what later came to be known as 'general linguistics,' except insofar as their methods and arguments presupposed certain assumptions about the 'nature' of language. One of their preoccupations was the historical task of 'reconstructing' the unattested ancestral language from which, they assumed, all Indo-European languages had sprung. In this respect, they placed previously inchoate discussions of linguistic origins on a new footing (*see* **Western Linguistic Thought Before 1800**).

The Neogrammarians

The Neogrammarians are seen as marking an 'advance' on Comparative Philology, inasmuch as they endeavored, in the mid 19th century, to establish 'laws' of linguistic development. Discovering 'laws' was then regarded as a *sine qua non* for setting up a 'science.' The principal figures in the Neogrammarian (*Junggrammatiker*) movement were acknowledged to be H. Osthoff (1847–1909), K. Brugmann (1849–1919), A. Leskien (1840–1916), and H. Paul (1846–1921). Their main claim to fame was their formulation of the principle that the 'laws' of sound change hold without exception. Thus if, for example, an intervocalic stop consonant becomes a fricative in one word, this is predicted to happen in all such words when that sound occurs in a similar environment in the same language. In this respect, the Neogrammarians supposedly brought linguistics in line with the 19th-century conception of the natural sciences. Osthoff spoke of the "blind necessity" with which sound laws operate. (Cf. the Newtonian law of gravitation.) The claim itself is virtually worthless, since any instance of an exception could always, for the Neogrammarians, be accommodated by *ad hoc* modification of the 'law' in question. We end up with mere statements of what has been observed to happen with regularity in the past. The exceptionless laws are no more than products of their own hind-sighted formulation.

Saussurean Structuralism

Although F. de Saussure (1857–1913) paid great respect to the Neogrammarians, his approach opened up a quite different chapter in academic language studies. The posthumously published *Cours de linguistique générale* (1916), based on lecture notes taken by his students at the University of Geneva, came to be regarded as the Magna Carta of modern linguistics. In this work, linguistics is presented as one branch of a more all-embracing study of signs, which Saussure referred to as 'semiology' (*sémiologie*).

Saussure did not believe in linguistic 'laws.' He saw 19th-century 'historical' linguistics as a muddle and thought that the Neogrammarians offered no insight at all into what a language was for its speakers. He accordingly drew a fundamental distinction between 'synchronic' and 'diachronic' linguistics. Synchrony is often equated, but mistakenly, with a study of the present-day language. Nor is Saussure's *linguistique diachronique* a synonym for *linguistique historique*, as will be evident to anyone who reads attentively the section on that subject in the *Cours de linguistique générale*. But it was often misunderstood by later linguistic theorists.

Saussure did not mount an all-out attack on comparative and historical linguistics, but he shunted those inquiries into an intellectual siding from which they could make no effective contribution to answering the main questions that linguistic theory had to tackle.

For Saussure, *linguistique diachronique* was an academic edifice set up by the linguist, with a perspective altogether different from that available to the individual member of a linguistic community at any one time. *Linguistique synchronique*, on the other hand, was an attempt to capture the psychological reality underlying the way a typical member of the linguistic community uses its communal language. This distinction was, and always will be, controversial. Saussure himself did not help matters by sometimes appearing to identify the synchronic viewpoint with that of the traditional (prescriptive) grammarian.

Saussure's distinction between *langue* (the collective language system) and *parole* (the linguistic act of the individual) also remained a bone of contention. Although Saussure neither coined nor used the term "structuralism," this was the label later attached to his conception of synchronic analysis. Its principal

feature is that forms and meanings (*see* **Western Linguistic Thought Before 1800**) are not to be identified by matching them with anything external to language (e.g., sounds or physical objects), but solely by reference to internal (structural) contrasts arising within the language itself. Thus, for example, the form of the English word /bat/ cannot be stated in terms of the sequence of sounds [bat] but only by listing the contrasts that distinguish this word from /kat/, /fat/, /hat/, etc. This, for Saussure, is a necessary consequence of realizing that different languages operate with different sets of phonological contrasts: there is no fixed and finite set of phonemes valid for all languages. Similarly, the meaning of a word like *horse* cannot be stated by identifying a certain species of animal and saying that *horse* is the name of this species. Why not? Because different languages recognize different biological species. Thus Saussure's view of meaning departed radically both from traditional lexicography and from that of the founder of modern semantics, his older contemporary M. Bréal (1832–1915). Saussure rejects the entire nomenclaturist approach to language entrenched in the Western tradition. It follows from this that all languages are irreducibly different. They are not just alternative ways of expressing some universal set of concepts, as Aristotle and many others had supposed.

By adopting this uncompromisingly holistic approach to linguistic analysis, Saussure in effect pulled the theoretical rug from under both Comparative Philology and historical linguistics as practiced by the Neogrammarians. His ideas were taken up and developed, particularly in Europe, by the so-called Prague school of linguistics. Two of its leading members were N. Trubetzkoy (1890–1938), whose work on phonology became highly influential, and R. Jakobson (1896–1983). Another branch of structural linguistics emerged in Denmark as 'glossematics,' whose leading exponent was the Danish linguist L. Hjelmslev (1899–1965). In France, G. Guillaume (1883–1960) was responsible for a highly original exploration of – and reaction against – some Saussurean ideas, in propounding what he called the 'psychomechanics' of language.

During Saussure's lifetime, two other approaches – linguistic geography and linguistic anthropology – came to prominence in language studies.

Linguistic Geography

In Europe, dialectologists began the task of documenting current linguistic usage and the geographical distribution of linguistic features. This led to the compilation of the first linguistic 'atlases.' The earliest (1881) was that of the German dialectologist G. Wenker, who sent questionnaires to 30,000 German schoolteachers in an attempt to survey features of local pronunciation. A Romanian linguistic atlas was published by G. Weigand in 1909, compiled on the basis of direct interviews with informants. In France, J. Gilliéron and E. Edmont published (1902–1910) a linguistic atlas based on interviews carried out at more than 600 localities. All this early work was done without the benefit of sound-recording apparatus and thus depended very much on the linguist's ear and the transcription system used. From it emerged, however, one new (and controversial) theoretical concept: the 'isogloss.' Isoglosses were lines drawn on a map, demarcating areas in which a particular feature occurred and separating those from areas of non-occurrence. The study of isoglosses in turn gave rise to controversial conclusions concerning the existence of 'dialects,' which, according to some investigators, proved to be illusory.

J. Gilliéron (1854–1926), on the basis of his cartographical studies, pronounced the 'bankruptcy' of traditional etymology and reached the famous conclusion that "each word has its own history." When this conclusion is combined with doubt about the existence of dialects, it leads directly to doubt about the existences of 'languages' too (*see* **Integrational Linguistics and Semiology**).

Linguistic Anthropology

In America during the same period, anthropologists provided a significant input to language studies, in particular under the auspices of the Bureau of American Ethnology. Attention focused upon the description and classification of native Amerindian (i.e., non-Indo-European) languages – a source of material unavailable in Europe. The study of these languages was also in part motivated by missionary activities and Bible translation – enterprises that played no comparable role in Europe. As early as 1838, the French scholar P. E. Duponceau (1760–1844) argued that all Amerindian languages had a basic grammatical structure unknown in the Indo-European family, and popularized the term 'polysynthetic' to identify it. In 19th-century language typologies, polysynthetic languages were often distinguished from 'synthetic' and 'analytic' languages. The characteristic of polysynthetic languages was said to be a tendency to prefer long, complex words that 'incorporate' a variety of grammatical distinctions. Thus, for example, in Eskimo a single word expresses the idea that might be rendered in English by the sentence "Do you think he really intends to go to look after it?" (The term 'incorporating' is also used to describe this type of structure.)

One result of this American anthropological tradition of language study was the publication of the *Handbook of American Indian languages* (1911–1922). The team responsible for this was led by F. Boas (1858–1942), a German scholar who had emigrated to the United States. The *Handbook* comprised brief descriptive accounts of the phonetics, grammar, and vocabulary of a range of Amerindian languages. Boas himself rejected the view that all Amerindian languages were 'polysynthetic.' His most important theoretical contribution to general linguistics is sometimes said to be his observation that Europeans were prone to misdescribe the sounds of Amerindian languages, because they could not avoid hearing them through the grid imposed by the phonetics of the European languages they themselves spoke. This idea has obvious links to Saussure's insistence that every language is structurally unique, although Boas arrived at this notion independently of Saussure.

In Europe, the chief influence of anthropology on the development of linguistics is to be seen in the work of the Polish anthropologist B. K. Malinowski (1884–1942), whose fieldwork in the Trobriand Islands inspired his view of language. Malinowski popularized the notion of "phatic communion," which, in contrast to the traditional idea that language existed to communicate 'thoughts,' emphasized the role of language as a mode of action for establishing social bonds.

Malinowski's ideas were taken up by J. R. Firth (1890–1960), professor of general linguistics at London University, whose ideas were in turn developed by 'neo-Firthians,' such as M. A. K. Halliday (b. 1925). Firth's 'polysystemic' linguistics emphasized the need for linguists to set up different 'systems' in order to describe relations between linguistic units at different 'levels.' Firth viewed linguistics as language "turned back upon itself." He is sometimes regarded as the archetypal 'hocus-pocus' linguist, for whom linguistics is a verbal game played in accordance with metalinguistic rules devised by the linguist (as distinct from 'God's-truth' linguists, who view their task as being to discover some external linguistic reality that exists independently of their inquiries).

Linguistic Relativity

Another line of thinking in which Saussurean ideas link up with those emanating from the American anthropological tradition of language study concerns the theory that came to be known as 'linguistic relativity' or 'linguistic relativism.' It is also known as the 'Sapir-Whorf hypothesis,' of which there are various versions.

The term *relativity* is often taken as alluding to the work of A. Einstein (1879–1955) in physics. In one sense, this is not misguided, inasmuch as Einsteinian relativity emphasized the dependence of 'facts' on the viewpoint of the observer. The Sapir-Whorf hypothesis does likewise. Einstein himself, however, was far from being a linguistic relativist. Another figure often invoked in connection with the Sapir-Whorf hypothesis is the German polymath W. von Humboldt (1767–1835), whose ideas are seen as anticipating the hypothesis, in that he associated each national language with a distinctive way of viewing the world.

E. Sapir (1884–1939) was a student of Boas's and published a study of Takelma in the *Handbook of American Indian languages*. B. L. Whorf (1897–1941) worked for the Hartford Fire Insurance Company and became a student of Sapir's at Yale. In his insurance work, Whorf was struck by the fact that accidents were often caused by the way things and situations were described. (For example, an oil drum described as 'empty' had actually been full of highly dangerous vapor.) In its most general version, the Sapir-Whorf hypothesis claims that the language we speak provides a linguistic lens through which we view the world. It follows from this that speakers of different languages see the world – and interpret their own experience of it – in different, incommensurable ways.

This is probably the most revolutionary idea to emerge from modern linguistics – revolutionary in the sense that it overturns the assumptions underlying the development of language studies throughout the Western tradition (*see* **Western Linguistic Thought Before 1800**). It also has far-reaching implications for linguistic epistemology. These implications tend to be ignored in mainstream linguistics, because they subvert the whole basis of establishing linguistics as a 'science.' Insofar as mainstream linguistics has an answer to the problems raised by the Sapir-Whorf hypothesis, it lies in mounting a rival hypothesis claiming that there exists at some 'deep' level in human psychology a universal grammar common to all languages (Chomsky, 1986). It is difficult to see how this conflict of views could ever be resolved by the adduction of empirical linguistic 'evidence.' The debate is ultimately sterile. Both the Sapir-Whorf hypothesis and the universal grammar hypothesis open up routes that lead linguistics nowhere. That has not prevented partisans on both sides from devoting much time and effort to driving their own hypothesis further into no-man's-land.

Behaviorism

In America Saussure's work remained for some time without noticeable influence, in part because

Saussurean linguistics eventually found itself under attack from psychologists, and in particular from linguists who had adopted the psychological doctrines of behaviorism. The leading linguistic exponent of these views between World War I and World War II was L. Bloomfield (1887–1949).

Although Bloomfield had himself studied Amerindian languages, and early in his career had been attracted to the psychological theories of Wundt, he was 'converted' to behaviorism at Ohio State University by A. P. Weiss (1879–1931). Bloomfield said of Weiss that he "was not a student of language, but he was probably the first man to see its significance" – an astonishing statement and an astonishing tribute. From the time of his acquaintance with Weiss, Bloomfield became increasingly and implacably opposed to 'mentalism' in linguistics. This entailed a rejection of Saussurean linguistics, given Saussure's view of the linguistic sign as a purely psychological unit existing in the human mind as a pairing of form (*signifiant*) with meaning (*signifié*). Somewhat more equivocal was Bloomfield's attitude to Boas's notion that linguistic structure lay below the level of human consciousness. Boas's introductory essay to the *Handbook of American Indian languages* had contained a concluding section on the "Unconscious Character of Linguistic Phenomena."

In accordance with behaviorist precepts, Bloomfield set out to banish from 'scientific' linguistics all appeal to unobservables. This meant no great loss as far as sound was concerned, since speech was audible and recordable. The problem lay with meaning. If meaning were in the mind of the speaker, they were unobservable and unrecordable. Accordingly, Bloomfield had to fall back on the ancient reocentrism of the Western tradition and declare that, for instance, the meaning of the word *salt* is nothing other than the physical substance salt. Thus meaning was rescued and brought within the domain of linguistic observation. The question then arose, however, 'What is salt?' Recognizing that linguists could not be expected to be omniscient, Bloomfield's answer was that meanings could not be stated precisely except in domains where science had 'determined' the nature of the thing in question. Thus science had determined that salt in the physical world is sodium chloride. So the semantics of words for substances like salt posed no problem. But science had not yet determined what items in the 'real world,' if any, corresponded to such words as *love* and *hate*. There, according to Bloomfield, semantics would have to wait until scientists had got round to investigating such matters. So semantics was "the weak point in language-study" and was likely to remain so "until human knowledge advances very far beyond its present state" (Bloomfield, 1933).

The effect of this behaviorist doctrine was to skew linguistic inquiry in the direction of phonetics, since so much of semantics lay in the limbo of the unknown or unknowable.

Distributionalism

Some of Bloomfield's followers drew the conclusion that a 'science' of language was possible only if it ignored the analysis of meanings and concentrated solely on the analysis of linguistic forms. The attempt to theorize this nonsemantic approach to linguistic structure came to be regarded as characteristic of American (as opposed to Saussurean) 'structuralism.' Saussure would have regarded any such development as retrograde, rather than as an advance in the science of linguistics. In effect, it was a reversion to Greek atomism (*see* **Western Linguistic Thought Before 1800**), although few if any of the American linguists involved were sufficiently well educated in the Classics to see the connection. Be that as it may, the outcome was a profound and misleading difference between the terms *structural* and *structuralism* as used in linguistics on either side of the Atlantic. Thus, for example, *Structural linguistics* (Harris, 1951) was the title of a well-known American textbook that (deliberately) excluded any consideration of linguistic meaning.

For the distributionalists, linguistic description consisted in identifying phonological units and defining all higher-order complexes by reference to the distribution of the basic units already defined. They assumed this could be done 'formally' – that is, without appealing at any stage to the supposed meaning of the items under investigation. The doyen of distributional linguistics was Z. S. Harris (1909–1992), whose critics argued that distributional analysis, contrary to its proclaimed principles, tacitly took meaning into consideration at every turn. In other words – so the argument went – the linguist's task of determining whether two sounds were the same or different was impossible without information about whether the native speaker treated them as articulating a minimal semantic distinction.

Distributionalism was 'formalist' in another sense. It reduced the definition of linguistic units to the sum total of analytic procedures involved in identifying them. Adoption of a different set of procedures might produce a different set of units. This in turn had implications for the status of linguistics as a 'science.' (The assumption was that 'scientific' knowledge should not be at the mercy of the methodological preferences of the scientist.)

However, at a deeper level, distributionalism also connected with the revolution in the epistemology of

science associated with Einsteinian relativity. In particular, the theory of operationalism in physics, as advanced by P. W. Bridgman (1882–1962), could be seen as a counterpart to Harris's distributionalism in linguistics. For Bridgman, all physical concepts were defined ultimately by reference to the techniques of measurement deployed in any scientific observation.

Generativism

One of Harris's students, A. N. Chomsky (b. 1929), proposed a novel approach to linguistic analysis by borrowing an idea from mathematical logic. It is possible to define a formal logistic system by setting out a string of 'rules' or algorithms that constrain transformations from one sequence of symbols to another. Chomsky saw that this procedure could be applied *in extenso* to the description of languages like English, if it were possible to propose a nucleus of symbols and transformational rules that would eventually 'generate' all and only the sentences of English. Many years of work were devoted to this Herculean quasi-mathematical labor, which never came to completion, either for English or for any other language.

Chomsky attacked behavioristic approaches to language, in particular the explanations offered by the experimental psychologist B. F. Skinner (1904–1990) concerning language acquisition. In the view of Chomsky and other generativists, language users were to be credited with reliable linguistic 'intuitions' as to the grammaticality or otherwise of expressions in their language. How these intuitions were to be distinguished from the products of teaching, rationalization, or personal preference was never clearly explained.

Although Chomsky at one point saw his project as a formalization of the Saussurean distinction between *langue* (= Chomskyan 'competence') and *parole* (= Chomskyan 'performance'), that would have amused Saussure, for whom the naïve notion that a language could be reduced to a set of sentences was not even a starter. Generativism has been criticized by sociolinguists (see the next section) for ignoring linguistic variation and verbal interactions in 'real-world' contexts. In particular, Chomsky's frequent appeal to an "ideal speaker-listener" is seen as an unacceptable evasion of linguistic issues that should be addressed empirically.

Sociolinguistics and Pragmatics

During the 20th century, there had also emerged in linguistics the simple but powerful idea that languages could be studied independently of any theory about "the language system." So it did not matter too much what theorists like Saussure or Bloomfield or Chomsky said. Whatever they said, linguistic behavior was still available for description as a social phenomenon. This is the basic idea behind what came to be called 'sociolinguistics.'

It derives from traditional dialectology, but it now incorporates the notion that linguistic variation has other than geographical parameters. In particular, it embraces the notion that there are discernible patterns of linguistic variation that depend on age, sex, education, social status, social occasion, professional occupation, and other factors. All these may intersect in numerous ways. It is the task of the sociolinguist to document, disentangle, and explicate these complex patterns.

A sociolinguistic approach leads on naturally to 'pragmatics' or 'pragmalinguistics.' This has now become a catch-all category embracing virtually all forms of linguistic variation or distinguishing characteristics that can be detected when language is used in a particular type of activity or communication situation.

The main objection that has been leveled against linguistic research of this kind is that it falls inevitably under the aegis or influence of sociology, and thus is led to adopt techniques of investigation and methods of classification that are approved in that discipline (in particular the adoption of certain social classifications and statistical assessments that may perhaps be inappropriate or misleading for linguistic purposes).

Speech-Act Theory

Pursuing a sociolinguistic approach to its logical conclusion, one is led to ask not "What are the basic sound units of a language?", nor "What are the basic grammatical units and constructions?", but "What are the basic speech acts by which one human being communicates with another?" Curiously, this question had been more or less neglected in modern linguistics until it was raised in the neighboring discipline of philosophy. That it was raised at all is due largely to the Oxford philosopher J. L. Austin (1911–1960), whose work in turn owes much to the climate of inquiry created in philosophy of language and philosophy of mathematics by G. Frege (1848–1925), B. A. W. Russell (1872–1970), G. E. Moore (1873–1958), and L. Wittgenstein (1889–1951).

The title of Austin's brief but highly influential book *How to do things with words* (1962) strongly suggests the pragmatic orientation of his thought. He

realized that stating a fact (recognized in traditional grammar as the province of the indicative mood) was only one of many verbal activities it was possible to engage in, even though it was the activity that traditional philosophy valued and paid attention to above all others. This led Austin to ask what other types of act were available to the speaker or writer. He pointed out that saying "I apologize" is not a description of an apology but the execution or performance of the act in question. This simple observation had escaped all traditional grammarians, for whom *I apologize* is on a par with any other first-person present indicative active, such as *I walk*.

Austin's initial exposition of the performative dimension in linguistic communication was followed up in work by J. Searle (b. 1932) and H. P. Grice (1913–1988). No comprehensive taxonomy of speech acts has been forthcoming. One reason alleged by critics of speech-act theory is that this is impossible, because speech-acts proliferate *ad infinitum*, depending on the criteria adopted for identifying them. Another, perhaps more damaging, criticism is that speech-act theory itself tacitly relies on accepting of the prior existence of a code (i.e., a language) by means of which the act is articulated. In other words, the speech-act theorist is led into complicity with the traditional assumptions of orthodox linguistics. Without these, the speech act cannot be identified or described.

Language Origins and Nonhuman Language

The ancient question of linguistic origins fell out of favor in the course of the 19th century. The Société de Linguistique, founded in Paris in 1866, expressly forbade the presentation of papers on the subject. The eminent American philologist W. D. Whitney (1827–1894) dismissed all discussion of the origins of language as "mere windy talk." Interest was renewed, however, in the 20th century, largely through research from two directions.

With the general acceptance of Darwin's theory of evolution, it seemed likely to many that language itself had developed from more primitive forms of communication used by less advanced ancestors of the human race. On this view, it ought to be possible in principle to account for language as having evolved on the basis of natural selection.

Others thought it more probable that language was the result of a unique genetic mutation. Others again maintained the skepticism of the 19th century and insisted that, in the present state of knowledge, it is impossible to progress beyond speculation to 'science.' The debate continues (Botha, 2003).

In the study of animal behavior, much attention was paid in the second half of the 20th century to the possibility of teaching linguistic skills to other primates, particularly those genetically close to *Homo sapiens*. It was generally accepted that apes were, for physiological reasons, unlikely to be able to produce articulated speech. But there seemed no reason why they might not master a language of gestures. Some of these projects developed systems based on American Sign Language for the Deaf. In later experiments, computer-monitored keyboards were used, and apes proved adept at mastering them.

From the beginning, work in this area was controversial. Skeptics questioned whether the use made by apes of the signs taught to them by human instructors was genuinely 'linguistic,' as distinct from being merely 'imitative.' (Pigeons had been taught to 'play ping-pong,' or at least to go through the motions, but no one seriously supposed that the birds understood what they were doing – i.e., playing a game.) However, it subsequently emerged that bonobos not only could use signs regularly to communicate their own wants, but could understand spoken English of a certain degree of grammatical complexity (Savage-Rumbaugh *et al.*, 1998).

Retrospect

When one looks back at the ambitious academic program that Saussure (1916) first laid out for modern linguistics, it is interesting to note what progress has been made. The program had three objectives. There is still a long way to go in pursuing Saussure's first goal of describing all known languages and recording their history. His second goal, of determining the forces operating permanently and universally in all languages, is no nearer to fulfillment, because of fundamental disagreement about the methods to be pursued. His third goal, that of defining and delimiting linguistics itself, threatens to disappear as the boundaries separating linguistics from neighboring disciplines become increasingly porous. The real weakness in Saussure's original program, as it now appears, was its failure to make provision for any study of the actual contexts in which linguistic communication is embedded. Such studies seem inevitably to involve trespassing on or borrowing from work done by specialists in adjacent fields. As a result, fewer and fewer linguists any longer believe in the autonomy of linguistics. It would be a more accurate reflection of current trends to say that across a wide spectrum of academic research in the humanities the importance of linguistic considerations is increasingly acknowledged, and the interdependence between verbal and nonverbal communication recognized.

It has almost become a cliché to say that new communication technologies are having enormous effects on political discourse. Examples of these effects abound, from the use of the Internet by democracy activists in China to its use in political campaigns in the United States. Discussion of the political impact of electronic communication and its implications intensified after September 11, 2001, with governments voicing fears that the Internet had become of tool for terrorist elements, and some citizens voicing fears that new regulations allowing the government to curtail freedom and privacy in cyberspace violated what they saw as the 'democratic ethos' of the medium.

The debate about the relationship between computer mediated communication and democracy has always been characterized by ambivalence and contradiction. Howard Rheingold, one of the earliest analysts of online community building, noted in the early 1990s that virtual communities could either assist citizens in revitalizing democracy, or become a substitute for democracy, luring users into attractively packaged forms of superficial discourse.

Linguists, discourse analysts, and scholars in communications studies have contributed to this debate in a number a ways, focusing on a wide range of issues, including code choice and the domination of English in electronic discourse, the norms of interaction that develop in online discussions, the ways the Internet has affected global and local flows of information and, in some ways, changed the nature of information itself, the ways the medium has contributed to the imagination of new communities and news kinds of social identities, especially for marginalized groups, and the new kinds of 'literacies' necessary for citizens in the electronic age. Scholars working in these areas have tended to eschew technological determinism, putting

forth positions that emphasize the complex interaction among language, culture, technology, economic forces, political forces and the contingencies of situated social interaction.

This article will provide a brief overview of the major issues in the above areas, arranged around the concept of 'participation.' New communication technologies provide new ways for people to participate in the political process, from macro-level participation of collective action and community building to micro-level participation, in what Goffman calls 'the interaction order.'

The Internet as Tool and Artifact: Competing Discourses

The first important distinction that needs to be made when discussing ways those interested in language and communication study the Internet is that between the study of discourse **on** the Internet and discourse **about** the Internet. Technologies, as Christine Hine points out in her book *Virtual Ethnography*, are both tools for communication and artifacts that we create through the symbolic meanings we invest in them. Lakoff and Johnson, as well as others, have reminded us of the importance the metaphors we use have in shaping the ways we interact with the world. In his book *Internet Dreams: Archetypes, Myths and Metaphors*, Mark Stefik presents a number of these metaphors along with examples of how they are used, including how they apply to the Internet: as 'a digital library,' 'a communication conduit,' 'an electronic marketplace,' and 'a collection of virtual worlds.' In the United States, the most powerful metaphor for the Internet has been that of the 'information superhighway,' and this metaphor has an important ideological effect in shaping government and industry policy towards the medium, in particular, focusing recourses on the development of the informational rather than the relational aspects of the medium and on conceptualizing it as a network for the transportation of goods and services, much like the interstate highway system.

In terms of its political uses, media and academic representations of electronic communication can be divided into two broad discourses, one utopian and the other dystopian. The utopian vision has focused on the Internet's potential to widen political debate by providing the resources for disseminating information to a greater number of people, providing a forum for debating policy, providing spaces for the development and the strengthening of communities, and providing more efficient means for citizens to interact with their governments. This discourse emphasizes both freedom (illustrated by the 'electronic frontier' metaphor) and democratic governance (illustrated by the 'electronic commons' metaphor). An example of this perspective can be seen in predictions, like those of political scientist Anthony Corrado's in his 1997 book *Elections in Cyberspace,* that the Internet would bring about "a revitalized democracy characterized by a more active informed citizenry."

The dystopian discourse, on the other hand, sees the Internet alternately as a tool of criminal elements such as pedophiles or terrorists and as a tool for governments or large corporations to expand their influence. Here, the main focus is on security, whether it be couched in questions of how to protect national security from online terrorists, how to protect the security of our children and families from sexual predators, or how citizens can secure themselves against the enhanced surveillance capacity the Internet has afforded to governments and corporations.

The importance of these discourses is not merely academic. They help to shape the kinds of material policies governments enact to regulate the medium, and help to shape the patterns of usage adopted by individuals and communities. The ways we use the Internet is always both reflective and constitutive of the tension between these two competing discourses.

Participation: Deliberation and the Public Sphere

Most contributions to the debate about the Internet and democracy from the field of communication studies have focused on macro-political issues. In this approach, participation is seen in terms of individuals and groups interacting with larger political institutions and media organizations, and the emphasis is on the ways the new flows of information the Internet makes possible are changing the way information is used and policy is made. Electronic communication is seen as having the potential to undermine hierarchical institutions on a grand scale, allowing for new forms of uncontrolled horizontal communication.

Characteristic of this approach is the work of Peter Dahlgren, who explores the way the Internet is changing what Habermas calls "the public sphere." For Habermas, the public sphere is made possible and maintained through flows of discourse; it is constituted by social interaction. Computers have had the effect of shifting these flows of discourse, opening up different kinds of access to discursive practices for more people.

Others have also focused on the potential for the Internet to foster democracy, examining the extent to which the medium fulfills Habermas's criteria for

democratic discourse due to its near universal accessibility, social decontextualization, lack of usage conventions, and the difficulty of enforcing censorship. The two areas that have been most thoroughly considered are the effect the Internet has on citizens' access to information and its potential to provide a medium for the kind of considered deliberation seen necessary for democratic decision making.

The major impact the Internet has had on the flow of information is decentralization; whereas in the past sources of information tended to be concentrated among a few major commercial and governmental outlets, the Internet allows those with limited resources to publish information, and for users all over the world to bypass traditional gatekeepers of information and avail themselves of primary sources and of a wide range of perspectives on these sources. This feature has proved particularly important in nations in which traditional media (newspapers, television) are tightly controlled by governmental or commercial interests.

Not only has information itself become decentralized, so has the power to decide what kinds of information are important and what kinds are not – the process of 'agenda setting.' In the past, large media corporations and governments perpetuated a top-down model of political discourse, in which those at the top of the information business held control over the public discussion. Now, even web pages run by individuals can have an enormous impact on the shape of the political debate. Two good examples from the United States are the way the right wing website *The Drudge Report* introduced a sex scandal into the public discourse that led to the impeachment of President Clinton, and the way the activist site *MoveOn* helped to mobilized public opinion against the impeachment process.

This fracturing of the information market has given rise to new genres. Perhaps the most dramatic development in journalism in the early 21st century has been the growth of 'web-logs' or 'blogs,' websites on which individuals filter, organize, and comment upon the information made available by more traditional media. Many of these sites offer users the chance to participate in this filtering process. One of the best examples is *Plastic*, a site that allows members to post links to interesting articles they have read on the web and to invite others to debate on them.

The extent to which these new forms of journalism will cultivate the kind of informed public often seen as necessary for democracy is uncertain. Just because a public has more information available to it does not necessarily mean it is more informed, and much of the information that circulates on the web can be inaccurate or biased. It is also possible that these new modes of participation can actually limit users' access to opposing points of view, their exposure to information more than ever defined by preexisting interests. Furthermore, even though weblogs and other interactive forums allow users to participate, there are still limits on participation that are determined by moderators' interests and biases.

Of particular interest to discourse analysts is the way the Internet is changing the nature of information itself, particularly in regard to time and space. Not only has electronic communication increased the amount of information available, it has also resulted in written texts being circulated in the public at a greater frequency than ever before. In his essay, 'The Frequencies of Public Writing,' John Hartly notes that on the Internet the speed at which texts are produced and consumed has speeded up, altering the ways people regard and use the information in these texts. This increased speed of information has effects on the political decision-making processes of both leaders and citizens, forcing them, in many cases, to make hastier decisions in response to the furious flow of information.

The nature of information as it manifests in electronic communication is also of concern to those interested in literacy and the kinds of information processing skills citizens will need in the new electronic age. In their book, *New Literacies*, Colin Lankshear and Michele Knobel enumerate some of these skills, from the more pedestrian, like sorting and evaluating information and participating discursively in online marketplaces like *e-bay*, to the more subversive, like 'culture jamming' at *ADBUSTERS*. Applied linguists and educationalists have engaged in a wide range of research on how students process and produce information using computers.

In his book, *The Electronic World*: *Democracy, Technology and the Arts*, Richard Lanham posits that the superabundance of information on the Internet and the new capacity for texts to be easily reproduced will result in fundamental changes in political economy and the democratization of education. At the center of these changes, he suggests, are those who will develop new ways to assist citizens in choosing and using electronic texts through the creation of what he calls "attention structures." The ability for humans to formulate new architectures for attention, particularly through higher education, he insists, will determine the extent to which information will be useful in nurturing democratic institutions.

Many argue that the increased exchange of information afforded by the Internet and the ability to filter and use this information are not in themselves sufficient to foster democratic participation, that a more crucial element is the opportunity for citizens

to engage in deliberative communication, the process of openly sharing ideas and debating upon them. Many journalistic, political, and governmental web pages provide opportunities for users to participate in deliberative discussions. Examples include the *WELL*, 'Table Talk' at *Salon*, 'The Fray' at *Slate*, and forums at *The New York Times*.

Although computer-mediated forums seem to have the potential to foster the kind of deliberative dialogue useful for effective democratic decision making, studies of various computer mediated forums, newsgroups, bulletin boards, and chatrooms using principles of discourse analysis, and conversation analysis have been fraught with contradictions. While early studies suggested that the lack of conventional social cues might inhibit deliberative discourse and the formation of relationships, later research suggested just the opposite, that synchronis and asynchronis computer-mediated communication are often more expressive communication or, what Walther calls "hyperpersonal communication." At the same time, it has been found, that computer-mediated discussions tend to be dominated by a few individuals, mostly men, that contributions tend to be short, with a high degree of value placed on rapid response, that online decision making tends to be more competitive than cooperative, and that users are often given to personal attacks and abusive language, possibly due to the anonymity afforded by the medium that may inhibit the development of or adherence to shared social norms. Successful electronic deliberation seems to be a feature of electronic communities with more stable membership that are able to coalesce around shared goals.

Participation: Communities, Marginalization, and Activism

Another important issue relating to electronic discourse and democratization is the way the medium makes possible new kinds of communities, social identities, and forms of political action, particularly for marginalized groups.

One of the most widely debated questions about the Internet has been its ability to foster electronic communities and the effects Internet use might have on real life communities. A famous early proponent of electronic communities was Howard Rheingold, who insisted that cyberspace provides individuals with the freedom to form their own communities free of physical and political limitations. The extent to which electronic communities have become a force for democratic participation is debatable. In many instances, particularly among those suffering from social stigma, such as people with HIV/AIDS, the Internet has made available the means to form important networks for social support and information sharing. Detractors worry that involvement in electronic communities may actually weaken democracy by diminishing people's involvement in real life communities. Despite such concerns, most studies, for example the 2000 study of the Pew Internet and American Life Project, have found that Internet use tends to enhance contact with one's physical community.

Related to the issue of communities is that of how people in socially or politically marginalized groups have made use of the discursive practices offered by the Internet to alter their social situations and engage in online political activism (or 'hacktivism'). Perhaps the earliest and most famous examples of a socially radical perspective on new technologies is the Cyberfeminism movement, best characterized by the writings of Donna Haraway and her theory of the 'cyborg.' Cyberfeminists see the Internet as freeing women (and men) from the limits of biology. It focuses on such aspects of electronic communication as the lessening of hierarchy and the nurturing aspects of virtual communities, claiming that the Internet will represent the death of patriarchy and the dawn of a postgender world. Other examples of the Internet being used to advance the agendas of marginalized communities include the creation of digital 'queer spaces' by gays and lesbians, and the use of electronic communication by democracy activists in places like China and Burma.

At the heart of the ability for the Internet to foster free speech and political activism is the fact that new technologies of communication fundamentally change how people are able to manage their identities in interaction. The Internet has altered what Saco calls "the politics of visibility" in two ways. On the one hand, it has increased the visibility of heretofore marginalized people and perspectives. On the other hand, it has facilitated free speech by providing people ways to conceal or alter their identities. Here we see one of the chief paradoxes of electronic communication in relation to democracy. The anonymity that is possible on the Internet can simultaneously facilitate free speech and democratic deliberation by creating conditions under which people feel more comfortable expressing themselves, and inhibit free speech and serious deliberation by creating the conditions under which people do not have to take responsibility for what they say. Thus, while the Internet is a bastion of free expression for the socially and politically marginalized, it is also a major forum for those who seek to further marginalize them – purveyors of racist, sexist, and extreme nationalist ideas and other forms of hate speech. Thus, while

the Internet can, in some ways, counter marginalization, in other ways it can contribute to it. In her book *Cybertypes: Race, Ethnicity, and Identity on the Internet*, Lisa Nakamura argues against the utopian myth of a 'raceless Internet,' claiming that the kinds of racism that exist in physical space are often mirrored, or even accentuated in cyberspace. Similarly, the linguist Susan Herring, in her studies of gender and online language use, has found that attempts by females to participate on an equal basis in online discussions are often ignored or delegitimized by male users. Others critical of the potential for the Net to foster new political identities point to the fact that the identities most Internet websites make available for their users are not empowering political identities, but rather consumer identities. Despite the use of cyberspace for political activism, 90% of all web pages are commercial in nature.

Finally, any discussion of marginalization would not be complete without mentioning the 'digital divide,' the fact that many people in the world do not have access to the material resources or the skills to take advantage of the new modes of political participation that the Internet affords. Of the world's online population, for example, 41% is in the United States and Canada, while only 4% is in South America. In the United States, in 2000, white and Asian American households had Internet access at more than double the levels of black and Hispanic households.

Participation and the Interaction Order

Most of the issues above focus on language and discourse and how they operate in cyberspace on the level of governments, social institutions, and communities. Answering questions about the effect of the Internet on political life, however, requires not just attention to the politics of governments and institutions, but also to the more local politics of everyday life. Perhaps the greatest impact that new communications technologies have had on politics has to do with the way they have altered what Goffman calls the 'interaction order' – the patterns of participation and power that we construct with others on a moment to basis in our everyday lives. One branch of sociolinguistics particularly concerned with this aspect of cyberspace is mediated discourse analysis. In their book *Nexus Analysis*: *Discourse and the Emerging Internet*, Ron and Suzanne Scollon argue that, while the role of the Internet in disseminating political information and facilitating organized political deliberation and action are certainly important, a much more important impact of the medium has been the way it makes possible new linkages of social practices and, through these, new identities. The Internet, they say, has altered the participation frameworks and power relations associated with face to face communication: people once separated by more stable social boundaries of age, power, and geographical location are communicating more, identities are becoming more fluid and contingent, and the distinctions between conversational topics and activities (such at work and play) are becoming blurred. What discourse analysts should focus on when studying the Internet, they insist, is not just the discourse that they find on it, but the kinds of everyday social actions it makes possible for users.

Related to this approach is a concern not just with what people do online, but with how Internet use alters physical spaces – not just geopolitical spaces, but more local geographies of homes, offices, schools, and coffee shops where computers are used. In his article 'The problem of context in computer mediated communication,' Rodney Jones explores this issue. More conventional notions of context from sociolinguistics and linguistic anthropology, he argues, need to be revised to take into account the ways technology allows users to strategically alter multiple spaces and enact multiple ways of being socially present. This layering of multiple contexts has fundamentally altered power relations in workplaces, schools, and livings rooms.

Any review of the impact of new communication technologies on democracy will inevitably raise more questions that provide answers. Much will likely change in the coming years in terms of the ways people communicate and the ways governments govern, and these changes will provide a rich source of study for those interested in language.

Modularity

R Carston, University College London, London, UK

Here is a general characterization of the concept of a mental module: it is a department of the mind that is dedicated to a specific domain of content and is largely autonomous from other departments of the mind. Possible content domains are visual perception, language, arithmetic, music, spatial orientation, social relations, and scientific reasoning, each of which may itself be made up of more fine-grained domains.

Although domain specificity and autonomy are central to any notion of modularity, there are also important differences in the kinds of mental structure that may be referred to as modules. The main distinction is between (a) systems of mental representations and (b) computational mechanisms (see Samuels, 2000). Modules of the first sort are sometimes called 'information' modules, 'Chomskyan' modules (after Noam Chomsky, who proposed such a modular view

of the human language capacity), or 'competence' modules. Modules of the second sort are computational devices, processing systems, or 'performance' modules. Of course, modular systems of both kinds often coexist. For instance, a modular system for performing arithmetic computations might call on a domain-specific system of arithmetic knowledge; similarly, a modular mechanism for comprehending language (a parser) might deploy the contents of a Chomskyan module of linguistic information (see Segal, 1996).

Chomskyan modules ('C-modules' hereafter) are domain-specific bodies of knowledge that underpin a cognitive capacity. In addition to the well-known case of linguistic knowledge (the phonological, syntactic, and semantic knowledge constituting an individual's language), plausible candidates for such competence modules are physical knowledge (knowledge of some of the properties of physical objects), biological knowledge (knowledge of some of the properties of living things), psychological knowledge (knowledge of some of the properties of human minds), and mathematical knowledge (knowledge of counting and numerical quantities).

However, there are bodies of domain-specific knowledge that do not qualify as C-modules. Consider, for instance, a child's beliefs about Batman or an adult's knowledge of British history. To count as a C-module, a knowledge system must meet two additional constraints. First, there must be restrictions on information flow (both the accessibility of the system's knowledge to other content domains and the effect of outside information on the system itself). Second, at least some subset of the knowledge comprising a C-module is innately given (hence universal). With regard to language, a strong case has been made for a universal grammar (UG), an innate system of mental representations, which is shaped by environmental input into a specific linguistic system (Chomsky, 1984; Chomsky, 1986). By analogy with UG, we can envision that each of the other possible C-modules mentioned above develops from an innate knowledge base: UPh, UBio, and so on.

Computational or performance modules ('P-modules' hereafter) are mechanisms that process and transform mental representations. They are only able to carry out computations on a restricted range of inputs, namely, those concerning a particular domain, and in processing these inputs they can only use their own proprietary principles and procedures (their own database, which may comprise a C-module). For instance, an arithmetic computational module will only provide solutions to arithmetic problems and will only use arithmetic operations to solve those problems. Fodor's landmark 1983 book on modularity focused on P-modules (while acknowledging the existence of C-modules), arguing in particular that language processing is a P-modular system.

In addition to the central properties of domain specificity and informational encapsulation, Fodor suggested a number of other criterial properties of P-modules. Like reflexes, they function mandatorily when presented with an appropriate input, and they are very fast in their operation; consequently, their output is relatively shallow. There are three criteria that reflect their innate basis, distinguishing them from learned habits (which may also be fast and automatic): neural localization, a relatively fixed ontogenetic pace and sequence, and characteristic patterns of independent breakdown. Fodor (1983) provides evidence that language parsing (or perception) has all eight of these properties, though others dispute this (Marslen-Wilson and Tyler, 1987).

The big question about the architecture of the human mind concerns the extent to which it is modular as opposed to employing domain-general principles and processes. Fodor's (1983, 1989, 2000) answer is that only input and output systems (roughly, the various perceptual systems, motor systems, and language) are modular. The central cognitive systems, responsible for belief fixing and reflective thought, are content general and highly sensitive to contexts and individual utilities. So, according to Fodor, they are nonmodular (global, isotropic) and, as a result, are beyond the reach of scientific investigation.

The strict Fodorian view of a module, with its application only to peripheral mental systems, is widely seen as too restrictive (Karmiloff-Smith, 1992; Sperber, 1996, 2005; Carruthers, 2003, 2004). From an evolutionary perspective on human cognition (Cosmides and Tooby, 1994; Sperber, 1996), what characterizes a mental module is that it is a special-purpose mechanism attuned to regularities in a particular domain, a biological adaptation selected for its efficiency in dealing with problems specific to that domain. It will tend to employ principles and heuristics that have evolved for the task at hand and are not applicable to problems outside its domain.

On this broader view of a mental module, human cognitive architecture is likely to be massively modular. Not only perception but also many central conceptual systems are modular (Sperber, 1996, 2002; Carruthers, 2003). One central inferential capacity that has received much attention as a likely modular system is 'mind reading,' that is, the capacity to attribute mental states such as intentions and beliefs to others on the basis of observed behavior (Scholl and

Leslie, 1999; Wilson, 2003). It is further claimed that the pragmatic capacity (that is, the ability to infer the intended meaning of communicative acts, whether verbal or nonverbal) is a sub-module of the mind-reading module, with its own special-purpose principles and mechanisms (Sperber and Wilson, 2002; Wilson, 2003).

Strong supporting evidence for any modularity claim comes from 'double dissociations,' where for one group of people a specific capacity (say, mind reading) is impaired while another (say, language) remains intact, and, for another group, the pattern is the reverse (see Shallice, 1988; Smith and Tsimpli, 1996; Wilson, 2003).

Parameters and Definitions

Modularity is an important concept relevant to a number of central debates in the cognitive and neurosciences, including theories of the structure of the mind/brain. Broadly speaking, modularity concerns the degree to which cognitive domains can be thought of as separable – i.e., whether they function independently of one another. Exactly what constitutes a module varies widely across disciplines and theoretical approaches.

The most explicit definition of modularity comes from Fodor (1983). In Fodor's view, a module is a perceptual input system that meets the following criteria:

(1) It is *informationally encapsulated*; other parts of the mind/brain cannot interfere with the internal functioning of a module. (2) The operations within a module are *unconscious* and not available for reflection. (3) Modules have *shallow outputs* – i.e., the intervening operations that give rise to output are not apparent from that output. (4) The operation of a module is mandatory – *obligatory firing*.

Four more criteria apply and are exclusive to the notion of 'innate' modules. Innate modules are (5) *localized* in particular brain areas, common to all individuals. They exhibit (6) *ontogenetic universals*; their development is bound to a given time schedule. Additionally, there are characteristic ways in which modules break down, giving rise to (7) *pathological universals*. Finally, innate modules are (8) *domain specific*. They operate exclusively on certain types of input; in Fodor's terms, modules have proprietary inputs.

Albeit the most explicit, Fodor's vision of a module is by no means unchallenged. Importantly, different definitions of what constitutes a module may include various combinations of these criteria (Elman *et al*., 1996). Also, some criteria may be more important than others, depending on the level of description: anatomical structure, computation, function, or knowledge. It is generally accepted that some form of modularity exists in the human mind/brain, but there is little agreement on what exactly that is, nor on the degree of fractionation. For example, there is little controversy regarding the notion that highly specialized areas of the visual cortex selectively process specific dimensions of the visual experience of color and orientation. However, for higher-level cognition, whether a specific brain region can be thought of as the 'language module' or the 'face module' involves more controversial questions.

Bearing that in mind, we find it more useful to think of Fodor's criteria as separable hypothetical parameters – as opposed to necessary criteria – that are important in theorizing about the architecture of the mind/brain. For the purposes of this article, we will focus on three crucial questions in the modularity debate that correspond to some of the parameters discussed. These questions are by no means exhaustive, but they capture key elements that are relevant to the field as a whole.

1. The question of localization: At what level is the brain modular?
2. The question of ontogenetic and pathological universals: When, and how, do certain functions become modularized?
3. The question of domain specificity: Are modules independent of one another?

The Theory and Methodology of Modularity: Logic and Assumptions

Before we discuss the key questions, it is important that we present the methodological framework most widely used in investigating modularity. As a theoretical construct, modularity is tightly linked to the field of adult neuropsychology and can be thought of as one of its axioms. The main objective of this discipline has been to use patterns of impairment in the adult to arrive at a theory of normal cognitive processes and brain structure. Modularity is also an important construct in the more recent field of developmental neuropsychology, where one of the objectives is to arrive at a model of the normal child state from patterns of developmental impairment. Of course, both adult and child neuropsychology share another important and practical goal of diagnosis and symptomology for clinical populations.

The single most important piece of evidence for functional modularity is deemed to be the existence of double dissociations (DD), of which different versions share an underlying logic.

The adult and child brain damage version: After brain injury, Patient A loses the capacity to perform task X but can still perform task Y. Another Patient, B, shows the opposite pattern, where he or she can perform X but not Y. In this case, researchers infer that functions X and Y are doubly dissociated.

A further inference is also often made – i.e., that the sites of lesion in Patients A and B are causal for functions X and Y respectively. Although worded to fit the single case, the logic of DD applies to group studies as well. There is considerable debate about whether single-case or group studies are more appropriate in investigating modularity (Robertson *et al.*, 1993; Shallice, 1988). Nevertheless, most of the issues discussed here apply equally to single-case and group studies.

The developmental disorders version: The extension of the adult DD logic to development is somewhat curious, since most conditions of developmental disorders are not associated with frank neurological lesions (despite differences in brain anatomy and physiology being extremely common). In the developmental case, the logic is modified: Child A has learned skill X but not skill Y. Another Child, B, has learned Y but not X. It is then inferred that skills X and Y are dissociated over developmental time.

Yet another, stronger version of DD is used to support a particular claim – namely, genetic modularity: due to genetic impairment, Child A fails to learn skill X but learns skill Y. Another Child, B, with a different genetic mutation, displays the opposite pattern, in that he learns Y but not X. In this case, researchers infer that skills X and Y map onto the mutated gene or specific set of genes in each case. The necessary module is hypothesized to be defective or missing and thus unable to develop the skill in question, as illustrated in the following claim:

> ... Overall, the genetic double dissociation is striking... The genes of one group of children [specific language impairment] impair their grammar while sparing their intelligence; the genes of another group of children [Williams syndrome] impair their intelligence while sparing their grammar (Pinker, 1999).

The different versions of the modularity claim, as applied to language, will be discussed in detail later. However, first it is important to examine the critical assumptions embedded in the logic of DD, which are often overlooked, and to determine whether these assumptions hold in each version of the modularity claim.

There are at least four critical assumptions: (1) that specific brain substrates underlie dissociable functional components – the *dissociability assumption*; (2) that there is a direct mapping between behavioral impairment and functional components – *the transparency assumption*; (3) that lesions or disorders cause the subtraction of the affected module, reflected in functional impairment on tasks relevant to that module, while all other functions operate normally – the *subtractivity or residual normality assumption*; finally, (4) that all cognitive systems are similar across individuals with individual differences being noncontributive – the *universality assumption*. In sum, a direct mapping between modules and behaviors is assumed.

The extension of the DD logic to cases of developmental or acquired disorders has a number of strong implications: (1) that the behavioral patterns in the adult case and in the child case share the same underlying cause – namely, the defective module in question; (2) that a static model can explain patterns of behavioral outcomes, deeming the developmental process itself to be a minor contributor; and (3) that pure cases, exhibiting selective deficit as in the adult, can be found in infancy and childhood. These assumptions and implications shape the kinds of inferences that are made from the data and will thus be evaluated in detail when we turn to our three main questions.

Localization: At What Level is the Brain Modular?

A certain function or domain is said to be localized if it is represented and/or processed in circumscribed regions of the brain. At the other end of the continuum is distributed processing, where multiple, potentially discontinuous brain regions are involved in the representation or processing of a given function. Localization is not necessarily held as a criterion for modularity. Some theorists distinguish between cognitive modularity (arising from cognitive neuropsychology) and neural modularity (arising from classical neuropsychology), where each is of more relevance to cognitive and neural theories respectively. In some strong versions of this distinction, the neural substrates of cognitive modules are deemed irrelevant (see Robertson *et al.*, 1993).

It is fairly widely accepted that adult neurological patients can in some circumstances exhibit deficits that can be described as selective. The accumulation of a significant body of data from brain damage, and more recently from imaging, has helped elucidate what the components of cognition might look like in the adult. Classic findings point to breakdown within the language domain, including grammatical processing in Broca's area, and comprehension and word finding in Wernicke's area. Face processing is another domain claimed to be carried out uniquely in a specific region of the brain – i.e., the fusiform gyrus.

The logic and assumptions of DD face a number of theoretical challenges. Modular analysis lends itself to vast flexibility in the face of inconsistent data; a modular framework can, without fail, carve existing modules into increasingly smaller components or

keep adding new modules to accommodate a given behavioral pattern. At the extreme, multiple modules the size of each tiny concept could be hypothesized (Sperber, 2002). This infinite decomposition is best exemplified by the modular analysis of the language function, where linguistic knowledge is separated from general cognition, and grammar from the lexicon (Pinker, 1999), with further decomposition of the lexicon into components for nouns and verbs, and nouns into separate modules for tools vs. utensils (Tranel *et al.*, 1997). This seemingly infinite refinement of cognitive architecture raises the possibility that it is simply the task demands themselves that can account for what is deemed to be a module, shedding doubt on the of modular theories.

Even more problematic for modularity is whether it can really be considered a data-constrained model at all. Finding the doubly dissociated components requires a model that defines *a priori* what the components are. Furthermore, it requires a model of how the tasks used to assess the integrity of a given component relate to that module. Shallice (1988) highlighted the circularity inherent in such an analysis:

> An argument to justify [modular analysis] could . . . proceed in the following way: "If modules exist, then . . . double dissociations are a relatively reliable way of uncovering them. Double dissociations do exist. Therefore modules exist." Presented in this form, the logical fallacy is obvious.

According to Shallice, the validity of this claim rests on the assumption that dissociations can arise only from damage to modular systems. Yet findings from neural network lesioning clearly demonstrate that selective deficits can arise not only from a modular structure but also from a distributed neural network architecture (for example, Plaut, 1995). In fact, Shallice presents a number of alternative theoretical possibilities of nonmodular architectures that would also give rise to double dissociations after impairment.

On empirical grounds, the classic conclusion that damage in specific areas produces selective functional deficit has been countered by numerous findings. In language, agrammatic patients showed some preservation of grammatical judgment, albeit at a fragile level (Wulfeck and Bates, 1991). Conversely, clinical populations with damage in areas other than Broca's exhibited agrammatic symptoms (Dick *et al.*, 2001). More generally, the standard association between damage to these areas and patterns of language breakdown does not hold consistently – i.e., damage to Broca's or Wernicke's areas is neither necessary nor sufficient to produce the classic symptoms (Goodglass, 1993). Similar conclusions come from reviews of brain-imaging studies of phonological speech processing where, across different studies, little overlap was found in the activated regions (Poepel, 1996).

Turning to the developmental literature, we observe that in normal circumstances, infants' brains become progressively specialized and localized in a relatively specific manner that might suggest predetermined modularity. On the other hand, many have argued that cases of acquired lesions in infancy and childhood pose a major problem for claims of prespecified modular architecture. Although reorganization post-injury is not viewed as an important factor in adult cases, plasticity and reorganization are the rule rather than the exception in childhood for both typical and atypical development. Research on vertebrate brains has elucidated the extent to which reorganization and compensation are possible (reviewed in Johnson, 2005). Experience-dependent plasticity appears to be a hallmark of the brains of our species.

Some general trends come from large longitudinal studies of individuals who suffered focal brain lesions before 6 months of age (Reilly *et al.*, 1998). Despite their lesions, the majority of these children still attained normal language skills. As a general trend, the effects of lesions in children were consistently different from the effects of acquired lesions in similar locations in adults. This challenges the notion that , in both the adult and child cases, a missing or damaged module causes the breakdown of separate cognitive components. This does not imply, however, that language developed in the normal fashion in these atypical circumstances. In fact, there are clear demonstrations that that is not the case. For example, for the majority of children with focal brain lesions, language acquisition was delayed. Another interesting example comes from patterns of language specialization of adults who suffered focal brain damage during childhood. There does not seem to be a uniform solution that the brain employed after damage; some individuals exhibited specialization for language production in the left hemisphere, others in the right hemisphere, and others bilaterally (Satz *et al.*, 1990).

For decades, much of neuropsychology has focused on where functions and behaviors are localized. Indeed, far more emphasis has been given to the *where* question at the expense of the *why* question. Beyond claims of genetic specification, very little is understood about why in default circumstances a region takes on certain functions and not others. An argument can be made that in normal circumstances, Broca's area may become specialized for language processing not because it is specifically designed

for language but partly because it is the area with the computational characteristics that are particularly well suited to deal with the requirements of this domain (Elman *et al.*, 1996). In other words, a 'domain-relevant' region becomes domain specific over developmental time (Karmiloff-Smith, 1998). Thus, many regions may initially compete for the processing of given inputs, with the special computational properties of one region ultimately winning out. However, a full specification of what those computational properties are is as yet largely unknown. We return to these issues in the final section, on domain specificity.

Ontogenetic and Pathological Universals: When and How Does the Brain Become Modular?

Thus far, the application of modular analysis to disorders acquired in adulthood and childhood does not necessarily imply genetic specification of a modular architecture. This is accepted even by those who are proponents of the applicability of the adult neuropsychological approach to the child (e.g., Temple, 1997). On the other hand, cases of developmental disorders with genetic etiology have been used to support claims of genetic modularity. The critical assumptions in the adult model – namely, *dissociability*, *transparency*, *and subtractivity* (*residual normality*) – are relevant here, too. The universality assumption has a stronger version, where the child's modular architecture is considered to be not only universal but also *prespecified*. The goal is simply finding out what that structure is. Furthermore, the same implications of the extension of the adult model to the child case hold here – namely, *shared causes*, *appropriateness of static models*, and *the existence of pure cases*.

Some of these claims seem to be supported by evidence from childhood disorders. For example, Temple (1997) described the similarity between behavioral profiles of adults and children with prosopagnosia, dyscalculia, and certain subgroups of dyslexia, where in some instances the behavioral symptoms were indistinguishable in the child and the adult. Interestingly, such similarities were clearest with respect to school achievement skills, like reading and mathematical abilities.

Additional claims for genetic modularity come from the study of Williams syndrome (WS) and specific language impairment (SLI). According to some authors, WS involves "striking preservation" of language and face processing alongside severe visuospatial deficit (Bellugi *et al.*, 2001). In some forms of SLI, grammar is severely impaired, whereas all other functions are claimed to be unaffected (van der Lely *et al.*, 1998). This has led to the conclusion that behavioral components in these cases are indeed dissociable (*dissociability*) and that performance in the unaffected domains is normal (*residual normality*).

In a stricter application of modular analysis, SLI and WS have been taken as a doubly dissociated pair of the rule-based vs. associative memory language systems, implying genetically specified modules for these two domains (Pinker, 1999). Evidence for this claim comes from investigation of English past-tense formation. Crucially, children with SLI do not exhibit the normal advantage for regular over irregular past tense (Ulman and Gopnik, 1999). Children with WS, on the other hand, are claimed to display a particular difficulty in generating irregular past-tense forms, whereas the regular forms are unproblematic (Clahsen and Almazan, 1998).

The vast majority of claims pertaining to genetic modularity have been challenged, particularly with respect to the utility of applying a strictly modular approach in investigating developmental disorders. There are, for example, some general arguments against the view of genetic modularity based on current understanding of how genes and the brain work. If modularity is genetic, then genes would have to specify the representational content of each module – an unlikely claim. Genes obviously contribute to behavioral outcomes, but it is more likely that the mapping between these is indirect and highly experience dependent. Instead of specifying domain-specific knowledge, genes are more likely to contribute to the formation of domain-relevant learning mechanisms, which are gradually refined by the ontogenetic process (Karmiloff-Smith, 1998).

In addition to these arguments, specific claims of *pure cases and residual normality* have been refuted by studies, for instance, of Williams syndrome. First, once fine-grained methods are used to assess participants, clear-cut selective patterns of impairment and sparing are no longer found. For example, Thomas and colleagues found subtle deficits in WS for *both* regular and irregular past-tense formation (Thomas *et al.*, 2001). Second, equivalent levels of performance may be achieved by atypical processing strategies. For example, face processing in WS seems to be driven by a featural rather than a configural processing strategy (Deruelle *et al.*, 1999; Karmiloff-Smith *et al.*, 2004). Moreover, different brain processes are involved in the albeit proficient face processing in WS (Grice *et al.*, 2001). Similar analyses have been conducted of persons with SLI, who – despite the name *specific* language impairment – consistently displayed subtle deficits in domains other than language (reviewed in Leonard, 1998).

Further arguments against genetic modularity can be made when we simultaneously consider typical and atypical language development. While it is true that there are clear developmental milestones in language acquisition (*ontogenetic universals*), there is also substantial variability in the rate and style or strategy of acquisition (see Bates and Goodman, 1997, for a review). If a defective grammar module explained SLI as well as individual differences in normal language learning, then we should see a bimodal distribution of language abilities, with genetic differences accounting for the separation between the impaired and unimpaired groups. But the distribution is normal, not bimodal (Bates and Goodman, 1997). Furthermore, if grammar and the lexicon were separate modules (Pinker, 1999), it would be difficult to explain the strong correlations between early grammar and early lexical ability, whereas growth curves for late and early talkers show that the level of grammatical complexity reflects lexical abilities and not chronological age (Bates and Goodman, 1997).

In sum, the use of developmental disorders as evidence for genetic modularity is, in our view, flawed.

Domain Specificity: Are Modules Independent?

The domain specificity question concerns the extent to which the operations of a proposed module, such as syntax, are special and exclusive to that domain. It is critical that the question is phrased in a relative, as opposed to a dichotomous manner, since it is clear that at some level of processing, the brain integrates information from various sources to produce coherent experience. Elman *et al.* (1996) pointed to a number of broad notions of domain specificity. Domains can be specific because they have specific input/output systems: visual cortical areas receive input from the retina, whereas auditory cortical areas receive input from the ears. Specificity may also arise because different problems require different behavioral solutions and/or different computational mechanisms. It is hardly surprising, then, that because a particular domain requires specific kinds of representations or behavioral solutions, domain specificity would seem to exist. The important question, however, is the extent to which computational mechanisms of a given domain are exclusive to that domain – i.e., modular – throughout development or in adulthood.

In a narrow interpretation of domain specificity, Fodor (1983) claimed that modules operate using specialized mechanisms dedicated to handling specific types of input, what he called "proprietary inputs." For example, speech perception is distinguished from general problem-solving ability, where speech perception involves computing what is heard, with little reflection or analysis of the problem domain of language in which it is used. Moreover, any module deemed to be innate is, by definition, domain specific. However, converging evidence from different areas of research reveals a more complex pattern of how different domains interact and become specialized.

1. Both infants and adults have shown remarkable skills in discovering patterns and regularities not only in linguistic input but also in the general auditory and visuospatial domains (Newport and Aslin, 2000). While we still have little understanding of how these are used in learning and processing language, and importantly, of the constraints on this type of learning, these findings indicate that domain-general abilities could and may well play a crucial role in organizing linguistic input.
2. Increasingly, evidence points to the involvement, in other, more general skills, of the areas classically thought of as uniquely housing domain-specific operations. With respect to language, Broca's area has also been implicated in a number of non-linguistic processes, including musical structure, general selection mechanisms, and imitation.
3. In certain cases, dedicated mechanisms appear to be the result of experience with a given class of stimulus. For example, behavioral and brain-imaging studies have shown that the experience of experts with various classes of stimuli (e.g., dog judges) or training with an artificial class of stimulus ('greebles') results in activation of areas in the fusiform gyrus, which was previously thought to be activated exclusively for faces (Gauthier *et al.*, 1999). So, additional factors, such as level of categorization and expertise, also modulate the involvement of the fusiform gyrus in the processing of visual stimuli.

The question of whether domain specificity is prespecified in the human brain as a result of evolution or arises during ontogenesis from experience-dependent processes, coupled with self-organizing cortical mechanisms, is still an open one. What is clear, though, is that patterns and regularities in the input can quickly and efficiently lead to progressive specialization of the brain. Evolution is more likely to have given rise to greater flexibility of learning than to increasingly complex prespecified modules (Karmiloff-Smith, 1992).

In cases of developmental disorders, the domain-specificity question has also been discussed extensively. In the genetic-modularity view, genes code for specific representations that are domain specific. The alternative view is that domain-relevant computations

early in development are better able to handle certain forms of input, and those become progressively specialized in close interaction with the environment (Karmiloff-Smith, 1992). The idea of progressive modularization forcefully challenges the notion that a static model can be used to explain development in both the typical and the atypical case. On the contrary, the developmental process itself is a major contributor to behavioral outcomes (Karmiloff-Smith, 1998). In support of this claim, brain-imaging data from infants and toddlers have shown that over developmental time, there is a pattern of very progressive specialization and localization of important functions for our species, such as face processing (de Haan *et al.*, 2002). In atypical cases, the origins of the behavioral profiles found later in development may stem from differential processing of input and utilization of different strategies beginning early in infancy.

A related hypothesis is that deficits in 'low-level,' perceptual mechanisms are contributing factors in developmental disorders. Some possible mechanisms are rapid auditory processing impairment in specific language impairment (Temple *et al.*, 2003), magnocellular system impairments in dyslexia (Stein, 2001), and attentional abnormalities in Williams syndrome (Brown *et al.*, 2003).

Some have challenged the view that low-level impairment can be viewed as causal in many of these developmental conditions (Rosen, 2003), because of the fact that such impairments are not found in all cases. The validity of this claim is difficult to assess, for a number of reasons. First, many developmental disorders are diagnosed based on behavioral impairment in a specific area; this sheds doubt on whether it is necessary to look for impairments in other domains, after having *a priori* excluded those whose impairment is less marked. Second, low-level problems need not exist throughout the entire life span. The crucial point is that their presence *early* in development may trigger cascading effects, the *indirect* results of which are found later in development. Third, even if not taken as singular explanatory factors, low-level impairments may play an important role in altering the experience of the child in the environment, providing a possible mechanism by which developmental outcomes are achieved.

In sum, converging evidence suggests that modules are the final outcomes of the developmental process, as opposed to prerequisites to it. Furthermore, the progressive development of modules, both in infancy and adulthood, is tightly bound to experience. Even in adulthood, experience continues to play a role in forming brain architecture and processing.

Concluding Remarks

We started this article with three questions relevant to the modularity debate. The question of localization: At what level is the brain modular? Second, the question of ontogenetic and pathological universals: When and how do certain functions become modularized? Third, the question of domain specificity: Are modules independent of one another? We aimed to provide insights into each of these questions, but current understanding of how the human brain organizes itself over time remains relatively limited. However, the substantial body of evidence in support of dynamic interactions in development, as well as plasticity, experience dependency, and very indirect gene-behavior mapping, enables us to arrive at useful reformulations for future modularity debates.

First, with respect to localization, the important question for future theorizing will be why is it that certain areas take on the functions they do in default circumstances, and why can other areas support the same functions with a fair degree of success in certain atypical circumstances but not others? With respect to ontogenetic and pathological universals, we need to ask: How can we characterize the developmental process in each case? How do altered sensitivities affect the developmental process and give rise to different phenotypic outcomes? With respect to domain specificity, future theorizing should focus on the following issues: Are there general principles by which our species handles and organizes input to produce coherent units and learn regularities? And finally, how do these domain-relevant mechanisms progressively give rise to the specialized and complex adult brain? In our view, these types of questions will further the modularity debate on the relations between syntax, the lexicon, and other cognitive domains, beyond the claims of adult neuropsychological models, and where the gradual process of development is center stage.

The Republic of Moldavia is a former republic of the USSR and has been independent since 1991. The population is estimated to be around 4.4 million (July, 2004). The national or official language is Moldovan, which is spoken by 64.5% of the population (1989 census). Moldovan is very similar to Romanian and is often classified as a dialect of it. Other languages spoken are Russian, natively spoken by about 13% of the population; Ukrainian (13.8%); Gagauz, a Turkic language (3.5%); and Bulgarian (2%). An even smaller section of population speaks Belarusian (Belarusan), Polish, Romani, German, and Yiddish.

Most Russians came to the country after it was annexed by the Soviet government in 1940 and after World War II. Before 1940, the country was ruled as a principality by Romania. After it was annexed by the Soviet government, there was forced Russification. Moldovan was claimed to be a language distinct from Romanian and was considered to be at least partially Slavic in origin and was spelled with the Cyrillic alphabet. The Latin alphabet was reintroduced in 1989. Since then, the role of Russian has diminished greatly, although it is still an important language in the northeastern Dniester region (together with Ukrainian), and it is also retained as the language of interethnic communication. The Gagauz region in the southwest of the country, where Gagauz is spoken, was granted autonomous status in 1994.

Hermann (Herman) Møller was born near Tønder, Denmark, just north of the German border, in 1850. He spent his childhood in the North Frisian islands, where he became fluent in North Frisian (Frisian, Northern), High and Low German (German, Standard and Plautdietsche), and Danish. While his early education focused on classical languages, his university studies concentrated on Germanic and Indogermanic. He earned a Ph.D. from the University of Leipzig in 1874 and conducted his postdoctoral studies (*Habilitation*) at the University of Kiel. In 1883 he joined the University of Copenhagen as an instructor, becoming professor of Germanic philology in 1888. He retired two years before his death in 1923.

Møller's earliest scholarly writings concerned Germanic reflexes of Indogermanic phonology. In 1883 he made a foray into Old High German poetics, followed by a description of North Frisian. Møller's best-known contributions to linguistics were in the fields of Indo-European phonology and classification. He provided proofs for the Indo-European ablaut that was proposed by August Schleicher and most thoroughly treated by Ferdinand de Saussure. In contrast to Schleicher, Møller argued that vowel irregularities, like those in such modern English sets as *bear*, *bore*, *borne*, *born*, *birth*, *burden*, and Scottish *bairn*, are not the product of decay from an earlier, more regular stage but reflect irregularities already present in the Indo-European root. He further proposed that the Indo-European root consisted of a single syllable, all else being derivational or inflectional morphology. The notion that ablaut was an old phenomenon in the Indo-European root facilitated the discovery of further 'regular irregularities' in IE reconstruction, though strict monosyllabicity was later rejected.

Though Møller initially held that regular vowel alternations had no consonantal equivalents, the search for such correlations was the focus of the last two decades of his career. Adding to the class of laryngeal consonants (*coefficients sonantiques*) identified by Saussure, Møller was able to analyze Proto-Indo-European initial vowels as reflexes of earlier laryngeals followed by vowels. He proposed that these laryngeals corresponded to consonants in Proto-Semitic, a relationship first asserted in 1863 by Rudolf von Raumer. *Semitisch und Indogermanisch* represents Møller's attempt to discover the rules governing the relationship between IE consonants and Semitic consonants. The work posited similarities between Semitic and IE root structure. The findings were based on the assumption that roots composed of similar consonants and having similar meanings are related and the corollary assumption

Møller's best-known contributions to linguistics were in the fields of Indo-European phonology and classification. He provided proofs for the Indo-European ablaut that was proposed by August Schleicher and most thoroughly treated by Ferdinand de Saussure. In contrast to Schleicher, Møller argued that vowel irregularities, like those in such modern English sets as *bear*, *bore*, *borne*, *born*, *birth*, *burden*, and Scottish *bairn*, are not the product of decay from an earlier, more regular stage but reflect irregularities already present in the Indo-European root. He further proposed that the Indo-European root consisted of a single syllable, all else being derivational or inflectional morphology. The notion that ablaut was an old phenomenon in the Indo-European root facilitated the discovery of further 'regular irregularities' in IE reconstruction, though strict monosyllabicity was later rejected.

Though Møller initially held that regular vowel alternations had no consonantal equivalents, the search for such correlations was the focus of the last two decades of his career. Adding to the class of laryngeal consonants (*coefficients sonantiques*) identified by Saussure, Møller was able to analyze Proto-Indo-European initial vowels as reflexes of earlier laryngeals followed by vowels. He proposed that these laryngeals corresponded to consonants in Proto-Semitic, a relationship first asserted in 1863 by Rudolf von Raumer. *Semitisch und Indogermanisch* represents Møller's attempt to discover the rules governing the relationship between IE consonants and Semitic consonants. The work posited similarities between Semitic and IE root structure. The findings were based on the assumption that roots composed of similar consonants and having similar meanings are related and the corollary assumption

that vowel changes and affixes affecting such roots are also related. Though Møller's conclusions were and are viewed guardedly, the depth and breadth of his undertaking provide evidence of a strong conviction in a relationship that has not yet been thoroughly proved or disproved.

Mon

J Watkins, School of Oriental and African Studies, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Mon is the principal language in the Monic subbranch of Mon-Khmer languages, which form the bulk of the Austroasiatic language phylum. The near-extinct language Nyah Kur, spoken in Thailand, seems to be similar to Old Mon.

Mon is spoken in Burma/Myanmar and Thailand. In southeastern Burma, the Mon-speaking population lives in the area from Thaton across the lower Salween river area and down the coastal strip as far as Ye. Mon villages are interspersed with those of Burmans/Bamar and Karen/Kayin. The speakers of Mon in Thailand are thinly scattered in provinces surrounding Bangkok.

It is very difficult to put a precise figure on the number of people who speak Mon, not least because there is a large category of people who identify themselves as ethnically Mon but who do not speak the language. A further problem is the general lack of demographic data. Bauer (1990) undertakes a detailed analysis of the available information and concludes that there are probably one million Mon speakers, though this figure incorporates various degrees of bilingualism. Most of the Mon-speaking population is bilingual in Burmese or Thai. Of this million, roughly 50 000 – about 5% – reside in Thailand, and the remaining large majority resides in Burma. In Thailand, Mon have become heavily culturally and ethnically assimilated through extensive intermarriage between Mon and Thai, although being of Mon descent seems to carry some prestige.

Many sources suggest that the use of Mon is in decline in Thailand and possibly also in Burma, though this may not in fact be the case; again, the information available is confusing and contradictory. It appears that Mon is not yet a dying language. Although the government in Burma may have restricted teaching and official use of Mon, there are many villages in the middle and lower parts of the Mon state in Burma in which Mon is the only language spoken by people who are mostly literate in Mon, and it is predicted that Mon will continue to be a significant language in the region. Literacy rates in Mon are skewed toward men, as literacy is supported by monastery teaching, which is only partly accessible to girls. Mon language education organized by the New Mon State Party in Burma may redress the balance.

Mon is the ethnonym by which the Mon refer to themselves. This name can be traced back to Khmer texts from the Sixth through the early twelfth-century Mon inscriptions at Pagan in Burma. The name 'Mon' – which in Mon is မန် / မ၊ / ဍောန် [mòn] – is derived from the Old Mon RMEÑ, attested in an inscription dating from 1102 C.E. The initial RM- simplified to M- around the sixteenth century. The other names by which the Mon are known are the Burmese term *Talaing* တလိုင်း, considered derogatory, and *Peguan*, a geographical–historical name derived from Pegu, the ancient Mon capital.

that vowel changes and affixes affecting such roots are also related. Though Møller's conclusions were and are viewed guardedly, the depth and breadth of his undertaking provide evidence of a strong conviction in a relationship that has not yet been thoroughly proved or disproved.

Mon is the principal language in the Monic subbranch of Mon-Khmer languages, which form the bulk of the Austroasiatic language phylum. The near-extinct language Nyah Kur, spoken in Thailand, seems to be similar to Old Mon.

Mon is spoken in Burma/Myanmar and Thailand. In southeastern Burma, the Mon-speaking population lives in the area from Thaton across the lower Salween river area and down the coastal strip as far as Ye. Mon villages are interspersed with those of Burmans/Bamar and Karen/Kayin. The speakers of Mon in Thailand are thinly scattered in provinces surrounding Bangkok.

It is very difficult to put a precise figure on the number of people who speak Mon, not least because there is a large category of people who identify themselves as ethnically Mon but who do not speak the language. A further problem is the general lack of demographic data. Bauer (1990) undertakes a detailed analysis of the available information and concludes that there are probably one million Mon speakers, though this figure incorporates various degrees of bilingualism. Most of the Mon-speaking population is bilingual in Burmese or Thai. Of this million, roughly 50 000 – about 5% – reside in Thailand, and the remaining large majority resides in Burma. In Thailand, Mon have become heavily culturally and ethnically assimilated through extensive intermarriage between Mon and Thai, although being of Mon descent seems to carry some prestige.

Many sources suggest that the use of Mon is in decline in Thailand and possibly also in Burma, though this may not in fact be the case; again, the information available is confusing and contradictory. It appears that Mon is not yet a dying language. Although the government in Burma may have restricted teaching and official use of Mon, there are many villages in the middle and lower parts of the Mon state in Burma in which Mon is the only language spoken by people who are mostly literate in Mon, and it is predicted that Mon will continue to be a significant language in the region. Literacy rates in Mon are skewed toward men, as literacy is supported by monastery teaching, which is only partly accessible to girls. Mon language education organized by the New Mon State Party in Burma may redress the balance.

Mon is the ethnonym by which the Mon refer to themselves. This name can be traced back to Khmer texts from the Sixth through the early twelfth-century Mon inscriptions at Pagan in Burma. The name 'Mon' – which in Mon is မန် / မဉ် / ဃောန် [mòn] – is derived from the Old Mon RMEÑ, attested in an inscription dating from 1102 C.E. The initial RM- simplified to M- around the sixteenth century. The other names by which the Mon are known are the Burmese term *Talaing* တလိုင်း, considered derogatory, and *Peguan*, a geographical–historical name derived from Pegu, the ancient Mon capital.

The records of Mon cover a period from the sixth century to the present day. Certain collections show the state of the language at various times. The best-represented historical periods are the eleventh and twelfth and the fifteenth centuries C.E. Modern Mon dates from the mid-eighteenth century onward. Mon has influenced the major languages of mainland Southeast Asia, in particular Karen, Burmese, and Thai, all of which borrowed words from Mon in the first half of the second millennium C.E.

Modern spoken Mon differs considerably from written, literary Mon in phonology, lexicon, and syntax, to the extent that it is possible to consider literary Mon a source of loanwords in spoken language, just as much as Pali and Sanskrit. Early descriptions of Mon tended to ignore the difference between the colloquial and literary forms of the language. The two appear to have diverged from the sixteenth century, and both forms of the language have developed independent inconsistencies but remain inextricably intertwined. This complex situation has resulted in a high degree of ambiguity and redundancy in the orthography. For instance, the initial consonant of the first syllable in a typical disyllabic word is frequently h- in spoken Mon, though this pattern does not occur in literary Mon, which, despite being archaic, is the basis of the written language. The initial h- may be etymologically derived from a large number of different consonants, and so historically inaccurate variant spellings are common. For instance, the word pronounced *hədoh* 'strain, filter, sift' may be written in nine different ways: ခရှိုဟ် KHAḌUIH, ဂရှိုဟ် GAḌUIH, ထရောဟ် THAḌOH, ထရှိုဟ် THAḌUIH, ထိုဟ် THḌUIH, ဒရောဟ် DAḌOH, ဖရှိုဟ် PHAḌUIH, သရှိုဟ် SAḌUIH, and ရှိုဟ် SḌUIH. Literary Mon is an artificial construct that does not make sense without reference to spoken patterns. The mixture of the two forms has been described by the Mon scholar H. L. Shorto (1962: xvi) as 'a confusing scatter of seemingly aimless variation.'

Colloquial Mon exists in a range of dialects in Thailand and Burma, although all are mutually intelligible. The variety of Mon described here is that of Shorto's *A dictionary of modern spoken Mon* (1962), which corresponds mostly with the Mon Rao of Nai Pan Hla's *An introduction to the Mon language* (1989), spoken by Mon in Burma.

There are a number of Mon language sites on the Internet. Some are associated with Mon political organizations, and some with news and information, such as ကော /kaowao/ *Kao Wao* ('black cuckoo') and သွံ်ငတိုင် /hnɔŋ taŋ/ *Guiding Star.* At the time of writing, Mon language is not included in Unicode or other international standards, and so, Mon text is displayed on the Internet as graphics.

Like the scripts used to write Burmese, Shan, and certain other languages of Burma/Myanmar, Mon is written with a script derived from the Indic scripts that spread with Buddhism to continental Southeast Asia in the early part of the first millennium C.E. The Mon were the dominant group in the south of an area that now straddles the border between Thailand and Burma/Myanmar and were centered in two areas, one along the Chaopraya River in Thailand, and the other in the Moulmein–Pegu (Mawlamyine–Bago) area of lower Burma, with a principle center at Thaton on the east coast of the Gulf of Martaban.

The oldest Mon inscription, found at Lopburi in Thailand, dates from the eighth century and is written in the Southern Indian Pallava script. Because there are inscriptions in Pyu, an important language of the period, which predate those in Mon, it may be that the Mon borrowed the writing system from the Pyu. However, given, first, that Mon script bears a closer resemblance to Pallava script, and second, that the Mon city Thaton was itself a major Buddhist center, it may be that the Mon borrowed the writing system directly from India independent of the Pyu. It is thought that Mon scribes brought to the city of Pagan after the Mon were defeated by the Burmese king Anawratha in 1057 C.E. resulted in Mon script being adapted to write Burmese, though this theory has been disputed in recent research.

The Mon writing system is essentially the same as the Burmese one in appearance, but with certain modifications and some elements unique to Mon. The system is best suited to writing the Indic languages for which its parent scripts were first designed, such as Pali and, with a few extra symbols not shown here, Sanskrit.

Table 1 The consonants of Mon transliterated and transcribed; consonants associated with second ('chest') register are bold

ဥ	ဦ	◌ု	◌ူ	U	Ū
ဧ	အဲ	◌ေ	◌ဲ	E	AI
ဩ	အော်	◌ော	◌ော်	O	AÓ
အံ	အး	◌ံ	◌း	AṀ	AḤ

Mon is not a tonal language like its geographical neighbors, but vowels in Mon occur mainly in pairs distinguished only by a quasitonal distinction known as a register distinction, which is found in many Mon-Khmer languages, including Wa and Cambodian (Khmer). First or 'head' register is characterized by clear voice quality and is associated with more peripheral vowels; second or 'chest' register is characterized by breathy voice (transcribed here with a grave accent, `), a general laxness of the speech organs, and centralization of the vowels.

The consonants of the Mon writing system are set out in Table 1. As in Cambodian (see Henderson 1952), each consonant is associated with one of the two registers, and the reading of a vowel in a given context is determined by the register designation of the consonant that governs it – usually the initial consonant of a syllable. The minimal pair in Table 2 illustrates the contrast.

Mon, like many Mon-Khmer languages, has a rich array of vowels. The word-initial and word-internal vowel symbols of Mon are shown and transliterated in Table 3. Table 4 shows how each of these is pronounced in head and chest register.

One of the distinctive features of Mon-Khmer phonology is the prevalence of relatively unrestricted initial consonant clusters. Mon is no exception, though as mentioned above, in the colloquial language many such clusters are not pronounced as spelt. Mon script

Table 4 Mon vowels in head and chest register

First ('head') register			*Second ('chest') register*		
Mon	*Translit.*	*Pron.*	*Mon*	*Translit.*	*Pron.*
ကာ	KA	kaʔ	ဎ	GA	kɛ̀ʔ
ကာ	KĀ	ka	ဎါ	GĀ	kɛ̀a
ကိ	KI	kɔeʔ	ဎိ	GI	kìʔ
ကီ	KĪ	kɔe	ဎီ	GĪ	kì

ကူ	KŪ	kao	ဎူ	GŪ	kù
ကေ	KE	ke	ဎေ	GE	kè
ကဲ	KAI	koa	ဎဲ	GAI	kòa
ကော	KO	kao	ဎော	GO	kɔ̀
ကော်	KAO	kao	ဎော်	GAO	kɛ̀a
ကံ	KAÓ	kɔm	ဎံ	GAÓ	kɔ̀m
ကး	KAḤ	kah	ဎး	GAḤ	kɛ̀h

Translit. = transliteration; Pron. = pronunciation.

writes the second element of such clusters with a subscript form of the consonant, as shown in Table 5.

In addition to this already rich inventory of open syllable vowels, Mon features a large array of additional syllable rhymes that involve further diphthongs and final consonants (see Nai Pan Hla [1989]) for further details.

The following example sentences in Mon illustrate some of the basic properties of Mon syntax. Modifiers generally follow what they modify (1); SVO (subject–verb–object) order is observed (2); subject pronouns are dropped (3). Unusually for the languages of mainland Southeast Asia, Mon makes only limited use of classifiers and has a system of plural marking.

(1) ရဲ အဲ
RAI AI
ròa ʔòa
friend I
'My friend'

(2) အဲ ရာန် ယာတ် မ္ဆ် အုပ်
AI RĀN YĀT MVAI 'UP
ʔòa ràn yàt mòa ʔup
I buy cloth one length
'I bought a length of cloth.'

(3) ဒ္ဓံင် ပ္ဍဲ ဍုၢ်င် လ္ဂုၢ်င်
DMÅÑ PḌAI DṬUÑ LGUÑ
mòŋ ɖoa ɖɜŋ təkɜ̀ŋ
live in town Rangoon
'(He) lives in Rangoon/Yangon.'

History of Research

Much of the early work on Mongolic focused on the philological analysis of Written Mongol texts. Isaac-Jacob Schmidt, working in service to Russia, was the first to publish a scientific grammar and dictionary of Written Mongol in the 1830s. Linguistic work on living Mongolic languages was initiated in the 1840s by the Finnish ethnolinguist M. A. Castrén (who worked on Buryat) and continued in the late 19th and early 20th centuries by G. J. Ramstedt (on Khalkha, Oirat/Kalmuck, and Moghol), A. D. Rudnev (on dialects of Buryat and Mongol proper), Nicholas Poppe (on Buryat, Khalkha, and Dagur), and Antoine Mostaert (on Ordos). The documentation of Moghol was completed by Michael Weiers in the 1970s. The last major blank spot in Mongolic studies was the Shirongolic branch. After the pioneering contributions by Antoine Mostaert (Huzhu Mongghul) in the 1920s and 1930s, the Shirongolic languages were studied by a Sino-Russian expedition under the leadership of B. Kh. Todaeva in the 1950s and by an Inner Mongolian expedition in the 1980s. Even so, material on some Shirongolic languages and dialects has been extremely scarce until the present day. The last major Mongolic language to be documented was Minhe Mangghuer, described by Keith W. Slater (2003). The most up-to-date general work, with grammatical sketches of all Mongolic languages, was edited by Juha Janhunen (2003).

In the field of diachrony, the focus was long on external comparisons in the Altaic framework. The main source on Mongolic comparative studies remains the work of Nicholas Poppe (1955), which, unfortunately, has already become obsolete in some respects, especially as far as the languages of the Shirongolic branch are concerned.

Mon-Khmer Languages

G D S Anderson, University of Oregon, Eugene, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

The Mon-Khmer languages constitute a disparate group of languages belonging to the Austro-Asiatic phylum spoken in a large area across Southeast Asia. The term 'Mon-Khmer' has several interpretations. One sense in includes all non-Munda Austroasiatic languages (except Nihali if this is in fact to be considered Austroasiatic at all; for more *see* **Austroasiatic Languages**). Another sense of Mon-Khmer excludes Nicobarese, while a further interpretation excludes both the Nicobarese and the Aslian branches. This latter one is the understanding of the term 'Mon-Khmer' relevant for this article.

Within this narrow-scope interpretation of Mon-Khmer, the following subgroups can be reckoned: Bahnaric, Katuic, Khasi(c), Khmeric, Khmuic, Monic, Palaung-Wa, Pearic, and Viet-Muong. The internal relations of these subgroups have yet to be adequately determined to the satisfaction of specialists; as such, no *Stammbaum* of Mon-Khmer can be here offered.

One proposal (Grimes, 2000) on the internal subgrouping of Mon-Khmer within the broadest understanding enumerated above, recognizes a major cleavage between Aslian and all other Mon-Khmer languages; these latter are further subdivided into an Eastern Mon-Khmer subgroup consisting of Bahnaric, Katuic, Khmer, Pearic, Monic, and Nicobarese and a Northern Mon-Khmer group that consists of Khmuic, Khasic, Palaung-Wa, and the isolate Mang of Vietnam. Viet-Muong is considered a separate branch coordinate with other Mon-Khmer subgroups. In addition, a number of relatively recently identified Mon-Khmer languages of China and Vietnam either appear to be isolate branches or remain unclassified, e.g., Palyu or Bugan. These are briefly discussed below. Lower-level taxonomic subgroupings have also been offered, e.g., Katuic-Bahnaric within the Eastern Mon-Khmer branch. Further research will refine and revise the classification and internal relations of the Mon-Khmer languages.

However, given the controversial nature of all but the highest-order taxonomic subdivisions within Mon-Khmer, a conservative approach is offered here.

Within the context of individual subgroups of Mon-Khmer, comments are offered below on total numbers of speakers, etc. However, a few general overall comments on certain salient linguistic features can be made. Many Mon-Khmer languages exhibit unusual or noteworthy phonological features, such as the predilection to 'sesquisyllabic' (one-and-a-half-syllable) words that consist of a major/full syllable and a minor/reduced syllable. This takes the shape of reduced + full (or minor + major) and yields words with atypical clustering in initial position; examples can be found even in the names of several Mon-Khmer languages (or subgroups), e.g., Khmer, Khmu, Sre, Mnong, Mrabri, etc., Vowel systems among Mon-Khmer languages are frequently highly developed, with elaborate systems of back unrounded vowels, centralized vowels, etc. often in combination with various phonation types or register phenomena. Such phonation types include creaky voice, breathy voice, etc. This combination of large core vowel systems and phonation types yields exploded inventories of syllable nuclei and/or vowel phonemes in various individual Mon-Khmer languages. These rank among the largest, if not the largest, such inventories in the languages of the world.

While the phonological systems of Mon-Khmer languages are highly developed, the languages are relatively impoverished morphologically and tend toward isolating word structure. However, the presence in most languages of lexicalized derivational elements, as well as productive or active systems in such languages as Bahnar, suggests that Proto-Mon-Khmer may have been more morphologically rich than most of its daughter languages. Indeed, a range of affixational processes may be used in individual languages within the Mon-Khmer language family, such as the following examples of derived nouns from Palaung (Milne, 1921: 74–75): *ra-pʌn-hwɔːi* [NOM$_1$-NOM$_2$-finish] 'completion'; *pʌn-ra-iːr* [NOM$_2$-NOM$_1$-hate] 'loathing, abhorrence'; *ra-ka-rɔt* [NOM$_1$-NEG-arrive] 'the not arriving'; etc. Morphologically rich verbs are also to be found in individual Mon-Khmer languages, as is found in the following Khasi form:

(1) yɑ-pɨn-sɑm-θyɑʔ
RECIP/DIST-CAUS-INCLIN-*sleepy*
'together make (others) feel sleepy'
(Nagaraja, 1985: 27)

Similar morphologically developed verb forms may also be found in such Mon-Khmer languages as Katu and Bahnar. Indeed, it is possible to find cognate processes of affixation across several branches of the family, which may thus be reconstructed back to the Mon-Khmer protolanguage. Such is the case with the derivation of causative verbs. It appears that Proto-Mon-Khmer utilized a causative prefix when the verb stem was monosyllabic, but an infix when the stem was sesquisyllabic or longer. Such a pattern is found for example in Mon (Old Mon and modern Mon), the Katuic language Kuy, and Khmu. Note that the infix allomorph is realized as a (syllabic) nasal in Khmu and Kuy but as a schwa in Mon.

(2) Khmu
p-háan 'kill' *p-rəh* 'raise' *k-m-sés* 'drop'
←*háan* 'die' ← *rəh* 'rise' ←*k-sés* 'fall'
t-m-lùuy 'hang (something)'
←*t-luy* 'hang'
(Svantesson, 1983: 104)

(3) Spoken Mon: *p*-vs. -ə- (<*m/C__C)
hum ɗaik → *p-hum ɗaik* *klàŋ* →
'have a bath' 'bathe' 'be numerous'
hə-làŋ
'increase'
(Bauer, 1989: 90)

(4) Old Mon
kcøt → *kəcøt*
'die' 'kill'
(Bauer, 1990: 149)

(5) Kuy
kəcet → *kəmcet*
'die' 'kill'
(Bauer, 1990: 149)

This pattern is cognate with the system seen in Nicobarese and Proto-Munda as well, and as such appears to be a formation dating all the way back to the Proto-Austroasiatic level; see Anderson and Zide (2001) for more on this.

Syntactically, Mon-Khmer languages, like many languages of greater southeast Asia, possesses sequences of verbs commonly referred to as serial verb constructions (Schiller, 1990). Examples of a verbal sequence of this type includes the following from Khmer and Ravüa of the Palaung-Wa branch:

(6) Khmer
təu jɔɔk kɑsɑɛt mɔɔk
go take newspaper *come*
'go get the newspaper'
(Schiller, 1990: 40)

(7) Ravüa
ti me ho tɑw lik me pin ke-en
take you go send letter you accompany *to-here*
'go take the letter and come back'
(Schiller, 1990: 58)

Mon-Khmer languages are generally spoken in remote, hilly/mountainous, and isolated enclaves

spread across northern Thailand, Laos, Cambodia, southern China, Myanmar, northeastern India, and Vietnam. In many instances they are spoken by only a few hundred or few thousand speakers. However, Mon-Khmer languages are also the national majority language of both Cambodia (Khmer) and Vietnam (the heavily Sinicized Vietnamese).

Bahnaric is a large group of minority languages spoken in southern central Vietnam, southern Laos, and northwestern Cambodia. The total number of all Bahnaric language speakers is likely less than one million. There are three or four major subdivisions within Bahnaric. Bahnaric clearly has Northern, Western, and Southern branches, to which is added by some researchers a Central Bahnaric branch as well. The entire Southern subgroup is spoken in Vietnam, as are all but one of the Northern Bahnaric languages (Talieng is spoken in Laos). South Bahnaric is separated from the other Bahnaric languages by a group of Mainland Austronesian languages. West Bahnaric languages, on the other hand, are not found in Vietnam at all, but rather are dispersed throughout various enclaves in Laos and Cambodia. The Central Bahnaric languages, which includes Bahnar proper, is a disparate group of five languages scattered across Vietnam, Laos, and Cambodia.

(8) Bahnaric subgroups
- Northern Bahnaric
  - East: Cua, Kayong
    - Takua
  - West: Halang Doan
    - Jeh, Halang
    - Rengao
    - Sedang, Hre; Monom, Todrah
    - Unclassified: Talieng, Trieng
  - Unclassified: Katua
- Southern Bahnaric
  - Sre-Mnong: Mnong: Eastern Mnong
    - Central Mnong,
    - Southern Mnong
  - Sre: Koho, Maa
  - Stieng-Chrau: Chrau
    - Stieng (Bulo Stieng)
- Western Bahnaric
  - Brao-Kravet: Brao (Lave), Kravet, Kru'ng (Kru'ng 2), Sou
  - Laven: Laven
  - Nyaheun: Nyaheun
  - Oi-The: Jeng, Oi (Oy), Sapuan, Sok, The

Central Bahnaric
- Bahnar, Romam (Vietnam)
- Alak (Laos)
- Lamam, Tampuan (Cambodia)

Languages or dialects within these various headings include the following:

(9) Dialects/languages within various Bahnaric-speaking groups
- Stieng: Budip, Budeh, Bulach, Bulo (a.k.a. Ke-dieng, Se-dieng, and Rmang)
- Southern Mnong: Nong/Diq, Prong (Prang)/Rbut; perhaps also Rahong, Bu Sre
- Central Mnong: Preh, Budong, Burung, Dih Bri, Bunor, Biat
- Eastern Mnong: Rlam (Ro'lo'm), Gar, Kuenh, Dliê Ruc, Ndee
- Koho: Maaq, Sre, Töla, Nop, Köyon, Cil (Kou N'ho), Tring, Nohang, Lat/Lac, Riong, Pru, Laya, Röda, Co Don, Kalop
- Bahnar: Alakong, Tolo, Bonom, Golar, Jolong, Kontum, Röngao (Rengao), Kon KO De, Krem, Roh, To Sung, Hodrung, Hroi, 144 M'nhar
- Sedang: Central Sedang, Greater Sedang, Daksut, Kon Hring, Kotua
- Tampuon: Kroi, Lamam/Rmam

It is not possible to accurately gauge the exact number of speakers of Bahnaric languages, due in part to the extensive displacement many experienced during the Vietnam War. Many Bahnaric language speakers have been influenced by and/or shifted to national languages such as Vietnamese or Khmer or locally dominant languages such as Rhadé (Rade) or Cham (Austronesian). The following constitute rough estimates only:

(10) Estimated number of speakers of Bahnaric languages
- Koho 100 000+ (including 23 000–30 000 Sre, 30 000–40 000 Maaq, 14 000 Cil, 3000 Lac, 6000 Nop, 14 000 Riong, very few each of Laya, Co Don, Töla)
- Bahnar 85 000?
- Hre 80 000?
- Stieng 48 000?
- Sedang 40 000?
- Central Mnong 23 000?
- Chrau 20 000?
- Boloven (Laven) 18 000?
- Cua 15 000?
- Southern Mnong 12 000?
- Eastern Mnong 12 000?
- Halang 10 000?
- Jeh 10 000?
- Brau/Lavé 3000?
- Koyong < 3000?
- Nha Hön 2500??
- Todrah, Alak, Takua, Cheng, Sapuan, Oi, Souq, Pragar, Kayong, Bout, Duan ??

Note that Parkin (1991) considers Central Bahnaric languages to be North Bahnaric.

Katuic languages are spoken in the region where Laos, Cambodia, and Vietnam meet. There are two

subgroups within Katuic, conventionally called Eastern and Western Katuic. The total number of speakers of Katuic languages is approximately 200 000–300 000. The main languages include Katu, with 20 000–30 000 speakers, Bru, with possibly as many as 80 000 speakers, Sô (Tro), with 10 000 speakers, Pacoh, with 15 000 speakers, Ta'oih, with perhaps 10 000 speakers, Souei (Proom), with around 10 000 speakers, Kataang, with at least 10 000 speakers, Kaleung, who have mainly shifted to Lao but who number perhaps 40 000, and finally Kuy, with possibly as many as 150 000 speakers. Other than the Katu proper, the Pacoh (and the closely related Phuong), and the Khua, who live in Vietnam, and the Kuy and Western Bru of Thailand (and northern Cambodia), Katuic-language speakers live mainly in Laos. Many are undergoing shift to Lao.

(11) Katuic languages
- Eastern Katuic
  - Kasseng
  - Kataang
  - Katu–Kantu
  - Ngeq–Khlor–Alak 2
  - Pacoh–Phuong
  - Lower Ta'oih–Upper Ta'oih–Ir–Ong
  - Tareng
- Western Katuic
  - Kuy–Nyeu
  - Eastern Bru–Western Bru–Khua–Leun–Mangkong–Sapoin–So Tri–Sô

Khasi[c] is the only branch of the Mon-Khmer language family spoken in mainland India. For more details *see* **Khasi**.

Khmeric consists of two languages: Central or Standard Khmer, the national language of Cambodia, and Northern Khmer, spoken mainly across the border in Thailand. For more on Khmer *see* **Khmer**. Khmer has been attested since the 7th century and appears in at least four historical stages: Pre-Angkorian, Old Khmer, Middle Khmer, and Modern Khmer. There may be as many as seven million Khmer speakers.

The Khmuic subgroup of Mon-Khmer consists of approximately a dozen languages scattered across Laos, Vietnam, and Thailand, with small enclaves in Myanmar and China as well. The Khmuic branch is further subdivided into the following subgroups:

(12) Khmuic languages
- Khao
  - Khao (Vietnam)
  - Bit (Laos)
- Mal-Khmu
  - Khmu
    - Khmu (Laos, Thailand, Vietnam, China, [Myanmar])
    - Khuen (Laos)
    - O'du (Vietnam)
  - Mal-Phrai
    - Lua' (Thailand)
    - Mal (Laos)
    - Phrai (Thailand)
    - Pray (Pray 3) (Thailand)
- Mlabri (Thailand)
- Xinh Mul
  - Khang (Vietnam)
  - Pong (Phong Kniang) (Laos)
  - Puoc (Vietnam)

Apart from these designations, which are standard in the Western linguistic tradition, Khmuic-speaking peoples are known by a plethora of local variants (Parkin, 1991: 96). These include the folk-etymologized Kha Mu in Laos (*kha* is a general term for subjugated 'hill tribes' in Laotian), sometimes also Phou Theng or local designations such as Thay Hay or Hok in Laos and Rook in Thailand; in China they were formerly known as Chaman, now Kemu; in Vietnam, the Khmu are often referred to as Xa Cau. The total number of Khmuic speakers is moderately large, with Khmu proper the largest group, having between 350 000 and 500 000 total speakers in numerous local variants. Mal-Phrai, also known as T'in, has perhaps 20 000 speakers and is probably the next largest Khmuic-speaking group. Many languages are spoken by very small populations, e.g., Khang Ai of Tay Bac Province, Vietnam, which may have fewer than 1000 speakers; a similar number is estimated for Bit of northern Laos, while Mlabri (also known as Mrabri and Yumbri) may have as few as 200 speakers.

One group that deserves special mention here are the Lamet, who are sufficiently Khmuized linguistically and culturally to make their classification unclear. It is possible that they were originally speakers of a Palaungic language but their exact classificatory status remains open.

The Monic branch of Mon-Khmer consists of just two languages, Mon of Myanmar and Thailand and Nyahkur of Thailand. Mon, like Khmer, has a long literary tradition, with texts dating back 1000 years to the time when the Mon ruled an empire in this region; isolated inscriptional sources date back as far as the 7th century. Ethnic Mon may number nearly half a million, but the total number of speakers is significantly less, possibly only a tenth of that figure. The Nyahkur, on the other hand, total no more than a few thousand speakers, and probably represent the remnant of an old Mon kingdom of southern Thailand. In Thai they are called Chaubon; both ethnonyms mean 'mountain people.'

Members of the widespread Palaung-Wa branch of Mon-Khmer are found scattered throughout

Myanmar, Thailand, the Yunnan province of China, and Laos. The total numbers of Palaung-Wa speakers is likely over one million. Several divergent groups are to be found within this branch, the exact internal relations between which remain to be worked out to the satisfaction of specialists. The major languages or subgroups within this branch are Danau, the various divergent Angkuic groups, Palaung proper, Riang, and the large Waic group with multiple subdivisions. Some reckon an Eastern and a Western group, the former including Danau, Palaung and Riang, the latter consisting of Waic, Angkuic and possibly Lametic as well.

Palaung speakers, who fall into several dialect/language groups, are heavily influenced by Shan and undergoing linguistic assimilation to this Tai language. At least three Palaung languages are reckoned, viz. Pale (Silver), Rumai, and Shwe (Gold). The Palaung languages are mainly spoken in Myanmar, but each have a small number of speakers in China, where they are all united under the official De'ang nationality; Pale Palaung speakers are also found in Thailand. The total number of Palaung speakers is difficult to estimate but may be in the range of 500 000–600 000, or it may be much smaller. A divergent Palaung group, the P'u-man, are found in Yunnan, China. As this Chinese ethnonym refers to other groups as well, it is not known how many speakers of P'u-man are really to be found. Riang, like Palaung, is heavily influenced by Shan and rapidly losing its similarly small population of speakers. Danau is also severely endangered and could have as few as 2000 speakers, if that many, at present.

Lametic, as mentioned above, shows considerable influence from Khmuic and may not really belong in this branch of Mon-Khmer. It consists of Con, with perhaps 1000 speakers, and Lamet, with around 10 000 total speakers or maybe more.

The large and diverse Waic languages of Palaung-Wa constitute a heterogeneous group of languages spoken in enclaves throughout Myanmar and Yunnan, and originally in adjacent parts of Thailand as well. The number of Waic languages and its internal divisions remain open questions, despite considerable work by Diffloth in particular. Most Waic languages are spoken by small populations which range from less than 100 to more than 100 000. Wa is often known as Va in China; other common ethnonyms referring to Wa-speaking groups include (Parkin, 1991: 111): Vu, Vo, Lave, Ravet, Krak, Kut Wa, Hsap Tai, and Gaung-pyat (head cutting). One possible subgrouping of this group is as follows:

(13) Waic languages

Proto-Wa
- Wa of Drage
- Wa Proper
  - Wa of Davies
  - Wa of Milne
  - Other Wa
    - Southern Wa
    - non-Southern Wa
      - Kawa
      - non-Kawa
      - Tung Va Wa
      - Wa of Antisdel
      - 'Bible Wa'
      - Praok

NB: Names refer to authors who described these languages.

NB: Samtauic/Angkuic P'u-Man is not the same as Palaungic P'u-Man.

As with other Mon-Khmer subgroups, there is a proliferation of names associated with languages of this group. Thus, to Angkuic may be found such names as Hu, Kiorr, Kon Keu, Man Met, Samtao, Tai Loi, and U. To Waic also belongs the official minority Bulang (Blang) language of China; this officially recognized ethnic designation in China also subsumes many other related languages of the Waic group. The Ethnologue reckons only four other Waic languages, Eastern Lawa, Western Lawa, Vo, and Parauk. As in many areas, the language/dialect distinction is ill defined and subject to the whims or biases of individual researchers.

The important languages of the Pearic branch of Mon-Khmer were spoken by around 8000–10 000 people in Cambodia before the ravages of the Vietnam War and the subsequent terror imposed by the Khmer Rouge regime. Only a handful of speakers of the half-dozen or so languages may remain. The languages of the Pearic branch include Chhong

(Chong), known for its unusually developed system of register/voice quality contrasts characterizing its vowel system, Pear, Samre, Somray, Sa'och, and the poorly known Suoy (not to be confused with the Katuic-speaking group of the same name). Pearic peoples are dark skinned and have curly hair and as such were often discriminated against in Cambodia. Traditionally, the Pear proper were tribute payers of the Khmer in cardamom (Parkin, 1991: 68).

The large and diverse branch of Mon-Khmer known as Viet-Muong consists of an indeterminate number of languages spoken primarily in Vietnam and adjacent parts of Laos. First and foremost belonging to this branch is Vietnamese, far and away the Austro-Asiatic language with the most speakers, with perhaps as many as 60–70 million. In fact, Vietnamese has more speakers than the other 150-odd Austro-Asiatic languages combined. Highly divergent within the family, with a developed tone system, lack of minor syllables and monosyllabic structure, lack of affixation processes, and heavy lexical influence from Chinese, the Austro-Asiatic affiliation of Vietnamese was not established until relatively recently (and is still disputed by some). Among the other languages of the branch, Muong stands out with its 400 000–500 000 speakers. Most other Viet-Muong languages have between several hundred and several thousand speakers. Most are poorly known or are indeed unattested linguistically, save perhaps an isolated word list. These are conventionally divided into a Chut subgroup, consisting of Arem, May, Pakatan, Ruc and Sach; a Cuoi subgroup, to which belong Hung, Pong, and Tum; a Muong group, consisting of Bo, Kha Tong Luang, Muong proper, Nguôn, and another Pong; a small Thavung-Phon Sung (Aheu) group; Vietnamese; and the poorly known and still unclassified Tho language. Other languages not recognized by the Ethnologue belonging to Viet-Muong include Coi, Dan Lai, K'katiam-Pong-Huok (Thai Pong), Ly Ha, Ma Lieng, Nguoi Rung, Nha Lang, Tay Cham, Tay Pum, and Tay Tum (Ktum) (Parkin, 1991). Many Viet-Muong languages are undergoing rapid assimilation to Vietnamese. While included here, it is possible that Viet-Muong is not actually a subgroup of Mon-Khmer, but, like Aslian and Nicobarese, a separate subgroup of (non-Munda) Austro-Asiatic.

In addition to the subgroups of Mon-Khmer languages adduced above, there are a number of as yet unclassified or isolated groups as well. Most of these are relatively recently described minority languages from China and Vietnam in particular.

The Mang or Mang U of Vietnam and China number perhaps 1000 speakers. Mang has similarities with Khmuic and Palaung-Wa, more with the latter, but may constitute its own subgroup within Mon-Khmer.

The Palyu, who occupy the Guangxi–Guizhou border region of China, have also been recently identified as a Mon-Khmer-speaking group, the exact affiliation of which remains to be demonstrated. They are locally known as Lai (not to be confused with the Tibeto-Burman Lai Chin of Bangladesh and Myanmar).

Other recently discovered and as yet unclassified Austro-Asiatic languages of China possibly belonging to Mon-Khmer include Bugan, Buxinhua, Kemiehua, and Kuanhua. What little is known of these languages suggests that they may well be important for comparative Mon-Khmer linguistics.

There is a specialist journal devoted to the linguistic analysis of Mon-Khmer languages, *Mon-Khmer Studies*, where the interested reader may find a wide range of articles covering virtually every conceivable linguistic topic in the investigation of the languages of this family. The majority of articles are devoted to phonological analysis, as Mon-Khmer languages, as mentioned above, are particularly unusual in this domain. Among present-day specialists in Mon-Khmer linguistics, Gerard Diffloth deserves special mention.

Monotonicity and Generalized Quantifiers

R Cann, University of Edinburgh, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

Many quantified noun phrases give rise to entailment relations between sentences that differ with respect to some modification of a verb phrase in their scopes. Consider the following sentences:

(1a) No students laughed.
(1b) No students laughed loudly.

(2a) Every philosopher smokes.
(2b) Every philosopher smokes heavily.

Whereas Example (1a) entails Example (1b), this is not the case with Examples (2a) and (2b). On the other hand, Example (2b) *does* entail Example (2a), whereas Example (1b) does not entail Example (1a). The important property to note here is that in the (b) sentences, the verb phrases pick out a smaller set of entities than the (a) sentences do (those who laugh loudly constitute a subset of those who laugh, and the set of heavy smokers is a subset of the set of smokers). So, the truth value of a sentence with *No students* in its subject position is unaffected if the denotation of its verb phrase (VP) is reduced. At the same time, the truth value of a sentence with *every philosopher* as subject remains unaffected whenever the denotations of its VP is extended. These entailment relations are known as 'monotonicity' relations, and *no students* is said to be 'monotone decreasing' (MON↓); *every*

Monaco: Language Situation

With its 1.95 km^2 of almost totally urbanized territory, the principality of Monaco is the second smallest independent state in the world after the Vatican. In the hands of the Grimaldi family since the 15th century, the Monégasque state is located on the southeastern coast of France on the Mediterranean Sea near the border with Italy. The national language of Monaco is French, which is spoken by 58% of the population. Of the 32 270 inhabitants (July 2004), 99% are literate and 1879 deaf. Seventeen percent of the population speaks one of two Ligurian dialects: either Genoese (Genoan, Genovese) or Monégasque (Munegasc, Ventimigliese). Even though Ligurian is a language predominantly spoken in Italy, it is closer to Piemontese, Lombard, and French than standard Italian. Monégasque was at risk of extinction in the 1970s, but compulsory learning in schools successfully revived it. A further 15% of the population of Monaco speaks the Niçard (Niçois) variety of Provençal, which greatly influences the French of the Monegasque region. In fact, the Niçard-speaking community comprises mainly individuals of over 50 years of age, but Provençal is increasingly gaining status as a literary language. There is a strong demand for teaching in schools and books in Provençal. Monaco is a tax haven and this has attracted many foreign companies and individuals to the principality, with the result that a number of other languages, such as English and Italian, also are in current use. The nine radio and five television stations of Monaco are supplemented by broadcasts from France and Italy.

Sandwiched between Russia to the north and China to the south, Mongolia has an area of about 1.5 million square km and a population of about 2.6 million. Mongolia was the center of the Mongolian empire, which, under Genghis Khan in the 13th century, extended from the Chinese Sea to the Persian Gulf and the Black Sea, and was one the largest empires ever built. From the 17th century large parts of Mongolia were controlled by the Qing Empire. An independent Mongolian republic was founded in 1921 with Soviet backing, and Mongolia remained closely associated with socialist politics and the USSR until 1990, when multi-party elections were held. One result of Mongolia's turbulent history is that most languages of the country are also spoken in the neighboring countries Russia and China, and some even farther away, e.g., Kazakh in Kazakhstan. Mongolian can be divided into several varieties spoken by different groups.

The main and national language of Mongolia is Halh (or Khalkha) Mongolian, the variety of Mongolian on which modern literary Mongolian is based. Halh Mongolian is the language of about 90% of the population, and most speakers of other languages of Mongolia are bilingual in it, and use it for writing. Mongolian is written in three different alphabets: the traditional Mongol alphabet originally developed in the 13th century, whose use has increased during the 1990s; the Cyrillic alphabet, introduced in the 1940s with the advent of communism; and the Latin alphabet, which since 1990 is being used slightly more often, mostly for the writing of English words and phrases.

A variety of Mongolian closely related to Halh, Peripheral Mongolian, is spoken by over 3 million speakers in China, who are part of a large ethnic

From the 17th century large parts of Mongolia were controlled by the Qing Empire. An independent Mongolian republic was founded in 1921 with Soviet backing, and Mongolia remained closely associated with socialist politics and the USSR until 1990, when multi-party elections were held. One result of Mongolia's turbulent history is that most languages of the country are also spoken in the neighboring countries Russia and China, and some even farther away, e.g., Kazakh in Kazakhstan. Mongolian can be divided into several varieties spoken by different groups.

The main and national language of Mongolia is Halh (or Khalkha) Mongolian, the variety of Mongolian on which modern literary Mongolian is based. Halh Mongolian is the language of about 90% of the population, and most speakers of other languages of Mongolia are bilingual in it, and use it for writing. Mongolian is written in three different alphabets: the traditional Mongol alphabet originally developed in the 13th century, whose use has increased during the 1990s; the Cyrillic alphabet, introduced in the 1940s with the advent of communism; and the Latin alphabet, which since 1990 is being used slightly more often, mostly for the writing of English words and phrases.

A variety of Mongolian closely related to Halh, Peripheral Mongolian, is spoken by over 3 million speakers in China, who are part of a large ethnic

Mongolian group that is one of China's five official nationalities. There are also a few thousand speakers of Mongolian in Russia.

In addition to Mongolian, 10 further languages are spoken in Mongolia (Grimes, 2000). Except for Chinese (Mandarin, 35 000 speakers), Russian (4000 speakers), and Mongolian Sign Language, all of them are, like Mongolian, Altaic languages: Mongolian, Buriat (Buriat, Mongolia), Darkhat, and Kalmyk-Oirat belong to the Mongolian group, Evenki is a Tungus language, and Kazakh, Uyghur and Tuvin belong to the Turkic group.

Furthermore, all Mongolian languages except for Darkhat (4000 speakers), a more distinct variety of Kalmyk-Oirat, have further speakers outside Mongolia, mainly in China and Russia. Thus, Kalmyk-Oirat is spoken in Russia by 174 000 Kalmyk people, as well as by Oirat people in Mongolia (205 500) and in China (139 000). Buriat varieties exist in Russia (Buriat, Russia) and China (Buriat, China) in addition to the 64 900 Buriat speakers in Mongolia. Tuvin (27 000) is spoken by a much larger community of 206 000 in Russia. There are small communities of about 1000 speakers each of Evenki and Uyghur in Mongolia, matched by much larger communities in Russia and China. Finally, Kazakh has about 120 000 speakers in Mongolia, but is mainly spoken in Kazakhstan, where it is the official language.

The language of education is Mongolian at all levels of education, except in Kazakh-speaking areas, where Kazakh is used at the primary and, to a lesser extent, secondary level. The most widely taught foreign language has traditionally been Russian, but it is being replaced by English as a result of the increased orientation of the country towards the West. With the increase of the role of English, the Latin alphabet is being used slightly more often, for example, for names of foreign products or companies. The English-language newspaper *Mongol Messenger* is published weekly by the state-owned news agency Montsame.

Mongolic Languages

J A Janhunen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Definition

Mongolic is the technical term for the group of languages (conventionally also known as Mongolian) spoken by the linguistic descendants of the historical Mongols, a medieval ethnic group that created the political entity known as the Mongol Empire (early 13th to late 14th centuries). The historical Mongols were pastoral nomads who started their expansion from a relatively compact homeland centered in northeastern Mongolia and northwestern Manchuria, but under the Mongol Empire they were dispersed all over central and northeastern Asia, where populations speaking Mongolic languages still survive today. By the degree of dispersal and diversification, Mongolic may be characterized as a medium-large language family. The principal neighbors of Mongolic in premodern times have included Turkic (in the west), Tungusic (in the northeast), (Mandarin) Chinese (in the southeast), and Tibetan (in the south). There is also both direct and indirect information of a group of historical and protohistorical languages, termed Para-Mongolic, which were collaterally related to the language of the historical Mongols. Due to problems of deciphering and linguistic analysis, these languages have not yet been incorporated into the corpus of Mongolic comparative studies.

Distribution

The geographical core area of the Mongolic family coincides with the historical and geopolitical entity of Mongolia, covering both Outer Mongolia (the

Mongolian group that is one of China's five official nationalities. There are also a few thousand speakers of Mongolian in Russia.

In addition to Mongolian, 10 further languages are spoken in Mongolia (Grimes, 2000). Except for Chinese (Mandarin, 35 000 speakers), Russian (4000 speakers), and Mongolian Sign Language, all of them are, like Mongolian, Altaic languages: Mongolian, Buriat (Buriat, Mongolia), Darkhat, and Kalmyk-Oirat belong to the Mongolian group, Evenki is a Tungus language, and Kazakh, Uyghur and Tuvin belong to the Turkic group.

Furthermore, all Mongolian languages except for Darkhat (4000 speakers), a more distinct variety of Kalmyk-Oirat, have further speakers outside Mongolia, mainly in China and Russia. Thus, Kalmyk-Oirat is spoken in Russia by 174 000 Kalmyk people, as well as by Oirat people in Mongolia (205 500) and in China (139 000). Buriat varieties exist in Russia (Buriat, Russia) and China (Buriat, China) in addition to the 64 900 Buriat speakers in Mongolia. Tuvin (27 000) is spoken by a much larger community of 206 000 in Russia. There are small communities of about 1000 speakers each of Evenki and Uyghur in Mongolia, matched by much larger communities in Russia and China. Finally, Kazakh has about 120 000 speakers in Mongolia, but is mainly spoken in Kazakhstan, where it is the official language.

Definition

Mongolic is the technical term for the group of languages (conventionally also known as Mongolian) spoken by the linguistic descendants of the historical Mongols, a medieval ethnic group that created the political entity known as the Mongol Empire (early 13th to late 14th centuries). The historical Mongols were pastoral nomads who started their expansion from a relatively compact homeland centered in northeastern Mongolia and northwestern Manchuria, but under the Mongol Empire they were dispersed all over central and northeastern Asia, where populations speaking Mongolic languages still survive today. By the degree of dispersal and diversification, Mongolic may be characterized as a medium-large language family. The principal neighbors of Mongolic in premodern times have included Turkic (in the west), Tungusic (in the northeast), (Mandarin) Chinese (in the southeast), and Tibetan (in the south). There is also both direct and indirect information of a group of historical and protohistorical languages, termed Para-Mongolic, which were collaterally related to the language of the historical Mongols. Due to problems of deciphering and linguistic analysis, these languages have not yet been incorporated into the corpus of Mongolic comparative studies.

Distribution

The geographical core area of the Mongolic family coincides with the historical and geopolitical entity of Mongolia, covering both Outer Mongolia (the

modern independent state of Mongolia) and Inner Mongolia (an autonomous region within China). In terms of physical geography, this area comprises the steppes and adjoining forested highlands of the Mongolian Plateau, the Ordos region south of the Yellow River, and the Gobi Desert. In the north the Mongolic area extends to the Baikal region in the Siberian forest zone (Russia), in the east to the plains of the Manchurian provinces (China), in the south to the Gansu corridor and the Amdo (Kokonor) region (China/Tibet), and in the west to the Jungarian basin in eastern Turkestan or Xinjiang (China). Separate areas and relicts of Mongolic-speaking populations are found in Afghanistan and the Caspian region (Russia), as well as in some parts of middle Asia (Kazakhstan and Kyrgyzstan). The area of the historical Para-Mongolic languages was centered on southwestern Manchuria.

Time Depth

Mongolic (excluding Para-Mongolic) is a well-delimited family of a dozen closely related languages, which derive from a relatively shallow and dialectally coherent protolanguage, termed Proto-Mongolic. In view of the circumstances underlying the dispersal of the Mongolic languages, the diachronic depth of Proto-Mongolic must be less than 1000 years. Although Proto-Mongolic is, by definition, a hypothetical construction that can only be approached by the method of comparative linguistics, it must have been close to the language of the historical Mongols, also known as Middle Mongol, which is actually documented in a variety of sources contemporary with the Mongol Empire. To some extent, these sources illustrate the gradual dialectal diversification of Middle Mongol, which ultimately led to the separation into the modern Mongolic languages. Contacts between some of the individual Mongolic languages have continued until modern times, making their boundaries with one another, in some cases, fuzzy.

Genetic Status

Mongolic is often classified as a branch of the Altaic language family, which is also supposed to include Turkic and Tungusic, as well as Korean(ic) and Japonic (Japanese-Ryukyu). Although the conception of an Altaic genetic unity still has adherents, modern research has demonstrated that the relationships of Mongolic with the other languages of the Altaic complex are best explained in terms of a complex and multilayered network of historical and prehistorical areal contacts. Most important, Mongolic has over several millennia been in contact with Turkic (in the west) and Tungusic (in the east), resulting in a considerable corpus of shared structural properties and linguistic substance among all the three language families. This interaction has continued up to the present day in some regions (Siberia, Manchuria, Eastern Turkestan, and Amdo). On a higher level, Mongolic also belongs to the areal and typological context of Ural-Altaic, which in addition comprises the Uralic language family. Both Altaic and Ural-Altaic remain relevant (and still insufficiently understood) concepts of areal linguistics and typology, but in the genetic sense these terms may today be regarded as obsolete.

Classification

Due to the shallowness of Proto-Mongolic, the Mongolic languages are difficult to classify in terms of a clear-cut (binary) family tree. It is, however, possible to establish four relatively distinct branches of Mongolic (Table 1). Two of these branches comprise only one marginal language each: Dagur (Daur; in Manchuria) and Moghol (Mogholi; in Afghanistan), which also seem to be the two Mongolic languages most distant from one another as determined by the number of shared isoglosses. The two other branches may be called Central Mongolic and Shirongolic. Central Mongolic covers a large coherent area centered on Mongolia, but it is differentiated into five distinct, although closely related, languages: Khamnigan Mongol (in the northeast), Buryat (Russia Buriat, Mongolia Buriat, and China Buriat; in the north), Mongol proper (in the center and east), Ordos (Peripheral Mongolian; in the south), and Oirat (Kalmyk-Oirat; in the west). Shirongolic also comprises a cluster of at least five distinct languages in the Amdo (Kokonor) region: Shira Yughur (also known as East Yughur), (Huzhu) Mongghul (Tu), (Minhe) Mangghuer (Tu), Bonan (Baoan), and Santa

Table 1 Classification of the Mongolic languages

Branches		*Languages*	*Location*
1. Dagur(ic)		(1) Dagur	Manchuria
2. Central Mongolic	2.1.	(2) Khamnigan Mongol	Manchuria
	2.2.	(3) Buryat	Siberia
	2.3.	(4) Mongol proper	Mongolia
	2.4.	(5) Ordos	Ordos
	2.5.	(6) Oirat	Jungaria
3. Shirongolic	3.1.	(7) Shira Yughur	Amdo
	3.2.	(8) Huzhu Mongghul	Amdo
	3.3.	(9) Minhe Mangghuer	Amdo
	3.4.	(10) Bonan	Amdo
	3.5.	(11) Santa	Amdo
4. Moghol(ic)		(12) Moghol	Afghanistan

(Dongxiang). All of the Mongolic languages comprise a number of dialects and subdialects, some of which could linguistically also be counted as separate languages. Internal diversification is particularly conspicuous in Mongol proper, Buryat, and Huzhu Mongghul.

Typology

Proto-Mongolic may be reconstructed as a rather consistently agglutinative language with a sentence structure and suffixal morphology of the Ural-Altaic type. This conclusion is confirmed by actual information from Middle Mongol, and similar typology is still synchronically observed in both Dagur and the languages of the Central Mongolic branch. The two other branches of Mongolic have, however, undergone fundamental changes in their typological orientation. Moghol, under the influence of the local Iranian languages, has developed a large number of non-Mongolic features, including prepositions, conjunctions, and new inflexional categories. The Shirongolic languages, on the other hand, have been influenced by both local Chinese and local (Amdo) Tibetan in a complex framework of areal interaction that may be termed the Amdo Sprachbund (also known as the Qinghai-Gansu Sprachbund).

Literary Use

Since the time of the Mongol Empire, the principal literary language of Mongols has been Written Mongol (also known as Literary Mongol), written in a Semitic script adopted from the ancient Uighurs of eastern Turkestan. The early forms of Written Mongol were close to Middle Mongol, also recorded in other scripts, whereas the later forms become increasingly close to the spoken dialects of Mongol proper, the most important modern Mongolic language. An adaptation of Written Mongol known as Written Oirat was introduced as a written language of the Oirat speakers in 1648, but otherwise Written Mongol has been used by the speakers of all the Central Mongolic languages. Written Mongol was the official written language of Mongolia until the 1940s, and it still has an official position in Inner Mongolia. Outside of Inner Mongolia, it has, however, been replaced by new literary languages (in Cyrillic and Roman scripts) based on the local vernaculars.

Political Status

Written Mongol used to be one of the five official languages of the Manchu Empire of China (1644–1911), and it still remains one of the few minority languages in which public education is available in China.

The dominant spoken language of the Mongols in both Outer and Inner Mongolia is Mongol proper. The principal dialectal form of Mongol proper in Outer Mongolia is Khalkha (Halh Mongolian), which has been developed as a literary language (in Cyrillic script) since the 1940s and is today the official state language of Mongolia.

Within the Russian Federation (in Siberia), Buryat has an official status (including a literary standard in Cyrillic script) in the Republic of Buryatia and other Buryat administrative areas, whereas a diaspora variety of Oirat known as Kalmuck (or Kalmyk) has a similar status in the Republic of Kalmykia (in the Caspian region). Other Mongolic languages have no official position, but experiments with modern literary languages (in Roman script) for Shira Yughur, Huzhu Mongghul, Minhe Mangghuer, and Santa are being made.

Demography

The total number of Mongolic speakers today is ca. 5–7 million. Most of these speak dialects of Mongol proper, of whom ca. 2 million live in Mongolia and ca. 3–4 million in Inner Mongolia (and other parts of China). Other relatively large Mongolic populations are those speaking Santa (ca. 600 000), Oirat (including Kalmuck, ca. 300 000), Buryat (ca. 300 000), Dagur (ca. 100 000), Ordos (ca. 100 000), and Huzhu Mongghul (ca. 100 000). The other languages are spoken by considerably smaller populations: Minhe Mangghuer (ca. 30 000), Bonan (ca. 10 000), Shira Yughur (ca. 3000), and Khamnigan Mongol (ca. 2000). Moghol is spoken by only a few individuals, if any.

With regard to linguistic vigorousness, there are considerable differences among the Mongolic languages. Whereas Moghol is moribund or nearly extinct, some groups of Khamnigan Mongol and Bonan are still viable in spite of their small numbers of speakers. Huzhu Mongghul is rapidly declining, whereas Minhe Mangghuer seems to be stable for the time being. The numbers of Buryat, Dagur, and Ordos speakers are diminishing due to assimilation by Chinese, Russian, and Mongol proper. Mongol proper is also rapidly losing ground in Inner Mongolia due to assimilation by Chinese. In this situation, Santa, a little investigated Mongolic language spoken by a compact and mainly monolingual Moslem population, with a low general level of literacy and education, is possibly the most vigorous and demographically the most rapidly growing Mongolic language today.

History of Research

Much of the early work on Mongolic focused on the philological analysis of Written Mongol texts. Isaac-Jacob Schmidt, working in service to Russia, was the first to publish a scientific grammar and dictionary of Written Mongol in the 1830s. Linguistic work on living Mongolic languages was initiated in the 1840s by the Finnish ethnolinguist M. A. Castrén (who worked on Buryat) and continued in the late 19th and early 20th centuries by G. J. Ramstedt (on Khalkha, Oirat/Kalmuck, and Moghol), A. D. Rudnev (on dialects of Buryat and Mongol proper), Nicholas Poppe (on Buryat, Khalkha, and Dagur), and Antoine Mostaert (on Ordos). The documentation of Moghol was completed by Michael Weiers in the 1970s. The last major blank spot in Mongolic studies was the Shirongolic branch. After the pioneering contributions by Antoine Mostaert (Huzhu Mongghul) in the 1920s and 1930s, the Shirongolic languages were studied by a Sino-Russian expedition under the leadership of B. Kh. Todaeva in the 1950s and by an Inner Mongolian expedition in the 1980s. Even so, material on some Shirongolic languages and dialects has been extremely scarce until the present day. The last major Mongolic language to be documented was Minhe Mangghuer, described by Keith W. Slater (2003). The most up-to-date general work, with grammatical sketches of all Mongolic languages, was edited by Juha Janhunen (2003).

In the field of diachrony, the focus was long on external comparisons in the Altaic framework. The main source on Mongolic comparative studies remains the work of Nicholas Poppe (1955), which, unfortunately, has already become obsolete in some respects, especially as far as the languages of the Shirongolic branch are concerned.

Mon-Khmer Languages

G D S Anderson, University of Oregon, Eugene, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

The Mon-Khmer languages constitute a disparate group of languages belonging to the Austro-Asiatic phylum spoken in a large area across Southeast Asia. The term 'Mon-Khmer' has several interpretations. One sense in includes all non-Munda Austroasiatic languages (except Nihali if this is in fact to be considered Austroasiatic at all; for more *see* **Austroasiatic Languages**). Another sense of Mon-Khmer excludes Nicobarese, while a further interpretation excludes both the Nicobarese and the Aslian branches. This latter one is the understanding of the term 'Mon-Khmer' relevant for this article.

Within this narrow-scope interpretation of Mon-Khmer, the following subgroups can be reckoned: Bahnaric, Katuic, Khasi(c), Khmeric, Khmuic, Monic, Palaung-Wa, Pearic, and Viet-Muong. The internal relations of these subgroups have yet to be adequately determined to the satisfaction of specialists; as such, no *Stammbaum* of Mon-Khmer can be here offered.

One proposal (Grimes, 2000) on the internal subgrouping of Mon-Khmer within the broadest understanding enumerated above, recognizes a major cleavage between Aslian and all other Mon-Khmer languages; these latter are further subdivided into an Eastern Mon-Khmer subgroup consisting of Bahnaric, Katuic, Khmer, Pearic, Monic, and Nicobarese and a Northern Mon-Khmer group that consists of Khmuic, Khasic, Palaung-Wa, and the isolate Mang of Vietnam. Viet-Muong is considered a separate branch coordinate with other Mon-Khmer subgroups. In addition, a number of relatively recently identified Mon-Khmer languages of China and Vietnam either appear to be isolate branches or remain unclassified, e.g., Palyu or Bugan. These are briefly discussed below. Lower-level taxonomic subgroupings have also been offered, e.g., Katuic-Bahnaric within the Eastern Mon-Khmer branch. Further research will refine and revise the classification and internal relations of the Mon-Khmer languages.

Monotonicity and Generalized Quantifiers

R Cann, University of Edinburgh, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

Many quantified noun phrases give rise to entailment relations between sentences that differ with respect to some modification of a verb phrase in their scopes. Consider the following sentences:

(1a) No students laughed.
(1b) No students laughed loudly.

(2a) Every philosopher smokes.
(2b) Every philosopher smokes heavily.

Whereas Example (1a) entails Example (1b), this is not the case with Examples (2a) and (2b). On the other hand, Example (2b) *does* entail Example (2a), whereas Example (1b) does not entail Example (1a). The important property to note here is that in the (b) sentences, the verb phrases pick out a smaller set of entities than the (a) sentences do (those who laugh loudly constitute a subset of those who laugh, and the set of heavy smokers is a subset of the set of smokers). So, the truth value of a sentence with *No students* in its subject position is unaffected if the denotation of its verb phrase (VP) is reduced. At the same time, the truth value of a sentence with *every philosopher* as subject remains unaffected whenever the denotations of its VP is extended. These entailment relations are known as 'monotonicity' relations, and *no students* is said to be 'monotone decreasing' (MON↓); *every*

philosopher is 'monotone increasing' (MON↑). So a quantified noun phrase (QNP) is monotone just in case:

$$\text{QNP VP}_1 \vdash \text{QNP VP}_2,$$

where $\vdash$ is the entailment relation and the denotation of VP_1 contains that of VP_2 (decreasing) or vice versa (increasing). Some further examples of monotone-increasing quantifiers are shown in the following examples:

(3a) Proper names:
Kim sang loudly $\vdash$ Kim sang.
(3b) *Many N*:
Many lecturers eat a lot of chocolate $\vdash$
Many lecturers eat chocolate.
(3c) *At least n N*:
At least three cats were killed by the dog $\vdash$
At least three cats were killed.
(3d) *Most N*:
Most students passed with high marks $\vdash$
Most students passed.
(3e) *More than half of the N*:
More than half of the congregation came to church on time $\vdash$
More than half of the congregation came to church.

There are fewer monotone-decreasing quantifiers that do not directly involve a negation particle:

(4a) *Few N*:
Few lecturers eat chocolate $\vdash$
Few lecturers eat a lot of chocolate.
(4b) *At most n N*:
At most three cats were killed $\vdash$
At most three cats were killed by the dog.
(4c) *Less than half of the N*:
Less than half of the congregation came to church $\vdash$
Less than half of the congregation came to church on time.

Not all quantifiers are monotonic, however (represented as MON∼):

(5a) *Exactly n N*:
Exactly three cats were killed $\not\vdash$
Exactly three cats were killed by the dog.
(5b) *A few N*:
A few lecturers eat chocolate $\not\vdash$
A few lecturers eat a lot of chocolate.

Interestingly enough, it seems to be universally the case that 'simple' noun phrases – i.e., proper names, noun phrases consisting of a simple determiner plus noun, and quantifier noun phrases such as *everyone*, *no one* – are always monotonic. Only noun phrases containing complex determiners, such as *a few*, *exactly five*, *all but seven*, etc., may not be.

To give more precise definitions and to explore the properties of monotonicity, most semanticists follow Montague (1973) in taking QNPs as denoting **generalized quantifiers**. These are defined as higher order denotations, picking out sets of sets of entities, each set bearing some specified relation to the set of entities denoted by the common noun (phrase) in the QNP. Thus, *every philosopher* denotes the set of all sets that contain as a subset the set of philosophers. *Every philosopher smokes* expresses a true proposition, therefore, just in case the set of smokers is a superset of the set of philosophers, in which case $\|\textit{smoke}'\| \in \|\text{every philosopher}\|$ (where $\|\alpha\|$ represents the denotation of α). More generally, given a sentence consisting of a quantified noun phrase in subject position and some verb phrase, $\|\text{QNP VP}\|$ is then defined as being true just in case $\|\text{VP}\| \in \|\text{QNP}\|$.

The monotonicity properties of generalized quantifiers have been the object of considerable research within semantics since the seminal work of Barwise and Cooper (1981). Within this framework, the monotonicity property of a quantifier is easily defined. A generalized quantifier QNP VP is as follows:

(6a) MONOTONE INCREASING just in case whenever
$\|\text{VP}_1\| \in \|\text{QNP}\|$ then $\|\text{VP}_2\| \in \|\text{QNP}\|$
where $\|\text{VP}'_1\| \subseteq \|\text{VP}'_2\|$.
(6b) MONOTONE DECREASING just in case whenever
$\|V\,P'_1\| \in \|\text{QNP}\|$ then $\|\text{VP}_2\| \in \|\text{QNP}\|$
where $\|\text{VP}_2\| \subseteq \|\text{VP}_1\|$.

Quantified noun phrases may combine with the 'Boolean' connectives *not*, *and*, *or*, and these combinations may have an effect on the monotonicity of the resulting quantifier. For example, negation reverses the direction of the monotonicity of a quantifier, whether it is internal (corresponding to VP negation) or external (corresponding to the negation of the QNP).

(7a) Not all philosophers smoke $\vdash$ Not all philosophers smoke heavily.
(7b) All students don't like semantics $\vdash$ All students don't like formal semantics.
(7c) Few lecturers don't eat a lot of chocolate $\vdash$ Few lecturers don't eat chocolate.

Formally, negation of quantifiers can be defined as follows:

External negation :

$$\|\neg QNP\| = \{X \subseteq E | X \notin \|QNP\|\}. \tag{8a}$$

Internal negation :

$$\|QNP\neg\| = \{X \subseteq E | (E - X) \in \|QNP\|\}. \tag{8b}$$

To see the effects of these definitions, consider the negation of the quantifier *all N*:

(9a) $\|\text{all N}\| = \{X \subseteq E \mid \|\text{N}\| \subseteq X\} = \{X \subseteq E \mid \|\text{N}\| \cap X = \|\text{N}\|\}$.

(9b) $\|\neg\text{all N}\| = \{X \subseteq E | X \notin \|\text{all N}\|\} = \{X \subseteq E | \|\text{N}\| \cap X \neq \|\text{N}\|\}$
(external negation plus (9a)).

(9c) $\|\text{all N}\neg\| = \{X \subseteq E | (E - X) \in \|\text{all N}\|\}$
$= \{X \subseteq E | \|\text{N}\| \cap (E - X) = \|\text{N}\|\}$
$= \{X \subseteq E | \|\text{N}\| \cap X = \emptyset\}$
$= \|\text{no N}\|$
(internal negation plus (9a)).

To see that negation does indeed reverse monotonicity, consider how the definitions in Examples (8a) and (8b) affect a monotone increasing quantifier. Assume a QNP is MON↑ and that X and Y are arbitrary sets such that $X \subseteq Y$, so that 'QNP X' entails 'QNP Y' (where X and Y are VPs that denote X and Y, respectively). If $Y \in \|\text{Q}NP\neg\|$, then $(E - Y) \in \|\text{QNP}\|$ (by Example (8b)) and $(E - Y) \subseteq (E - X)$, so $(E - X) \in \|\text{QNP}\|$ and hence $X \in \|\text{QNP}\neg\|$. So 'QNP not Y' entails 'QNP not X,' as required. Analogously, if $Y \in \|\neg\text{QNP}\|$, then $Y \notin \|\text{QNP}\|$, so that $X \notin \|\text{QNP}\|$ and hence $X \in \|\neg\text{QNP}\|$. So 'not QNP Y' entails 'not QNP X,' and both forms of negation thus make a monotone-increasing quantifier into a decreasing one.

Note that because $\text{QNP} = \neg\neg\text{QNP} = \text{QNP}\neg\neg$, any decreasing simple quantifier is a negated form of a simple increasing one. This may explain why negating decreasing QNPs is generally ill formed, because the corresponding simple increasing QNPs could be used.

(10) *Not few students = Many students.

Monotonicity is maintained if two (or more) QNPs with the same direction of monotonicity are conjoined by *and* or *or*.

(11a) A student and every lecturer were snoring loudly ⊢
A student and every lecturer were asleep.

(11b) Bill or both women ran home quickly ⊢
Bill or both women ran home.

(12a) No student and not all lecturers were asleep ⊢
No student and not all lecturers were snoring loudly.

(12b) At most ten men or less than half the women ran home ⊢
At most ten men or less than half the women ran home quickly.

Again it is fairly easy to show that this must be the case using the formal apparatus of generalized quantifiers, given conjunction interpreted as involving set intersection and disjunction as set union, as in Examples (13a) and (13b):

(13a) $\| \text{NP}_1 \text{ and } \text{NP}_2 \| = \| \text{NP}_1 \| \cap \| \text{NP}_2 \|$.

(13b) $\| \text{NP}_1 \text{ or } \text{NP}_2 \| = \| \text{NP}_1 \| \cup \| \text{NP}_2 \|$.

We take the persistence of monotonicity properties with *and* as an illustration of how the proofs of these four theorems are established:

Assume that QNP_1 and QNP_2 are both MON↑ and that X and Y are arbitrary sets such that $X \subseteq Y$. If $X \in \|\text{Q}NP_1\| \cap \|\text{Q}NP_2\|$, then it must be the case that $X \in \|\text{Q}NP_1\|$ and $X \in \|\text{Q}NP_2\|$. So, by increasing monotonicity, $Y \in \|\text{Q}NP_1\|$ and $Y \in \|\text{Q}NP_2\|$. Hence, $Y \in \|\text{Q}NP_1\| \cap \|\text{Q}NP_2\|$. QED.

Barwise and Cooper (1981) suggest that coordination of noun phrases is constrained by monotonicity:

Co-ordination constraint: Two NPs can be coordinated by conjunction (*and*) and disjunction (*or*) iff they are both monotone increasing or both monotone decreasing.

(14a) No student and every lecturer liked the book.
(14b) Most students and every lecturer liked the book.
(14c) *No student and most lecturers liked the book.
(14d) *No student and a lecturer liked the book.

On the other hand, the connective *but* seems to require quantifiers with different monotonicity:

(15a) Every woman but no man agreed with the Prime Minister.
(15b) No student but most lecturers liked the book.
(15c) *Most students but every lecturer liked the book.

However, there are many counterexamples to these apparent constraints, so they cannot be adopted universally and some other explanation remains to be given for the ill-formed examples.

(16a) At least three cats and at most four dogs (were killed on this road last year).
MON↑ and MON↓

(16b) Bill and a few women (met in the pub).
MON↑ and MON∼:

Although the constraint against conjoining quantified noun phrases with different monotonicity properties cannot be maintained as a linguistic universal, there is one property that is fully robust. Negative polarity items such as *any* or *ever* are typically within the scope of negation (Examples (17a)–(17d) (Klima, 1964), but they also appear in the scope of certain types of quantified noun phrases that do not contain an overt negation marker (Examples (18a)–(18d)). The latter are all monotone-decreasing quantifiers and the generalization in Example (19) appears to be universally true (Ladusaw, 1983):

(17a) John didn't eat any chocolate.
(17b) *John ate any chocolate.
(17c) No students were ever early.
(17d) *All students are ever early.

(18a) At most five residents saw anything.
(18b) Few students fail any exams.
(18c) *Many students fail any exams.
(18d) Less than half of the congregation ever stays to the end of the service.
(18e) *Exactly five people ever sing loudly enough.

(19) Negative polarity items may appear in the scope of monotone-decreasing quantifiers but not in the scope of nonmonotonic or monotone-increasing quantifiers.

In the discussion so far, the monotonicity of quantifiers have been treated as referring to entailment relations involving increases or decreases in their **scope**, as denoted by a VP with which they may combine. Because quantified noun phrases consist of a determiner plus a common noun phrase, the latter, like verb phrases, are taken in extensional semantic theories to denote sets; the theory of generalized quantifiers conceptualizes **determiners** as denoting relations between sets:

(20) *DET*(*A*) (*B*), where *A* is the set denoted by the common noun phrase (the restrictor) and *B* is the set denoted by the verb phrase (the scope).

Given this view, it is natural to consider whether monotonicity applies not only to variations in the scope of a determiner but also in its restrictor. Clearly, this is the case, and restrictor (or left) monotonicity can be defined in the same way as scope (or right) monotonicity was defined for QNPs (some examples are given in Example (24)).

(21) A determiner DET is LEFT (or RESTRICTOR) MONOTONE INCREASING (↑MON) iff
DET N_1 VP ⊢ DET N_2 VP, where $||N_1|| \subseteq ||N_2||$.
A student with red hair is singing entails *A student is singing*.

(22) A quantifier DET is LEFT (or RESTRICTOR) MONOTONE DECREASING (↓MON) iff
DET N_1 VP ⊢ DET N_2 VP, where $||N_2|| \subseteq ||N_1||$.
No student failed their degree exams entails *No student of linguistics failed their degree exams*.

(23) A quantifier DET is LEFT (or RESTRICTOR) NONMONOTONIC (∼MON) iff
DET N_1 VP ⊬ DET N_2 VP, where $||N_2|| \subseteq ||N_1||$ or $||N_1|| \subseteq ||N_2||$.
Exactly five students failed badly neither entails nor is entailed by *Exactly five students of linguistics failed badly*.

(24)

↑*MON*↑	A, some, at least *n*
↓*MON*↓	No, less than *n*
↓*MON*↑	Every, all
↓*MON*↑	Not all, not every
∼*MON*↑	Most, many
↑*MON*∼	Some but not all
∼*MON*↓	Few
∼*MON*∼	Exactly *n*

Montague Semantics

Historical Background

Montague semantics emerged around 1970, and constituted a fundamentally new approach to the semantics of natural language. In order to understand the importance of this approach, it is useful to consider the situation in that period of some neighboring disciplines of semantics: philosophy of language, philosophical logic, and linguistics. These subjects are considered below, a more extended picture of the historical background is given by Partee and Hendriks (1997).

One of the subjects studied in philosophy of language was meanings of natural language, and these were (before 1970) sometimes represented in some or other logic. The mapping between a sentence and its logical representation was made in an *ad hoc* way; it was more or less stipulated which formula was the correct meaning representation of a given sentence. The situation could be characterized as follows: a 'bilingual logician,' who knew logic and who knew a natural language, provided the formula. It was noticed that there could be a large difference between the sentence and the formula, and a dominant view of these matters at that time was the so-called 'misleading form thesis,' saying that there is a sharp distinction between the grammatical and the logical form of sentences, and that the grammatical form disguises the logical form to such an extent that they cannot be related in a systematic way. It was sometimes even proposed to design for certain purposes an improved version of natural language in which the form does not obscure the meaning.

In philosophical logic there is a tradition to study words of natural language that are philosophically interesting. Examples are 'necessarily' and 'possibly.' Axiom systems for these notions were designed which expressed their properties. A jungle of systems of modal logics arose, motivated by different properties of embeddings of these notions. Kripke brought about, in the mid-1960s, an enormous change in this field. He introduced semantic models for modal logics, thereby making it possible to conceive modal logic in the same way as mathematical logic: as a formal language with a model-theoretic semantics. The variety of systems could be structured by conceiving them as expressing relations between possible worlds in a model.

Around 1960, Chomsky brought about great changes in linguistics by introducing mathematical standards of explicitness. He developed the tools for this (context-free grammars and transformations), and syntax became a flourishing branch of linguistics. There was some attention to semantic issues, such as whether transformations were meaning-preserving, or what would be the input for a semantic component, but the theory was a theory about syntax that did not deal explicitly with semantics.

These three lines were brought together by Richard Montague. He was a mathematical logician who had made important contributions to the foundations of set theory. He was attracted by Chomsky's formal treatment of natural language, but unsatisfied by its (lack of) treatment of semantics. Therefore he developed an alternative to the Chomskyan approach that satisfied his (logical) standards. He presented a fragment of English and provided it with a rigorous model-theoretic interpretation. Most important is the fact that the relation between a sentence and its meaning is defined in a systematic way. It became possible, for the first time in history, to calculate which meaning is associated with any given sentence, hence to make predictions concerning semantics.

By developing his grammar model, Montague provided evidence for his opinion that there is no important theoretical difference between natural languages and the languages studied by logicians: both can be dealt with using the same methods and with the same mathematical rigor (Montague, 1970a: 189; Montague, 1970b: 313; Thomason, 1974: 188, 222). The title of one of Montague's first publications on this subject provides clear evidence of his position: 'English as a formal language' (Montague, 1970a).

Aims

The aim of Montague semantics is to describe, predict, and explain semantic relations between natural language utterances, an aim it shares with other theories. In the present section, some important semantic relations between natural language utterances will be introduced by means of examples, viz. entailment, valid reasoning, synonymy, and ambiguity. The examples given here are realistic in the sense that they are treated within the field of Montague semantics, thus giving an impression of the variety of phenomena that are studied. The examples that occur without reference are within the fragment of Montague (1973), or are variants of such examples.

An important semantic relation is the 'entailment' relation between sentences, say A and B. This means

that whenever A is accepted as being true, B must also be accepted as being true, on grounds of meaning properties. Sentence (1) entails sentence (2):

(1) Mary is singing and dancing.

(2) Mary is singing.

This entailment, however, does not hold for all grammatical subjects: witness (3) and (4), where in fact the inverse relationship holds.

(3) No-one is singing and dancing.

(4) No-one is singing.

This means that the noun phrases have to be divided into two classes, one for which the entailment holds, and one for which it does not. Then one would like to have an explanation of why precisely *two girls* and *both girls* are in different classes (*Both/precisely two girls were singing and dancing*), and a prediction concerning compound terms like *few girls and many boys*. For an overview of properties of quantified noun phrases, see Keenan and Westerstahl (1997) *and* the article **Quantifiers: Semantics**.

An example of a different nature is the following. (5) entails (6) (see Dowty, 1979):

(5) John cools the soup.

(6) The soup cools.

Here, one would like to have a description of the relation between the meaning of *cool* as a transitive causative verb and *cool* as an intransitive verb. And one would like to know why the implication holds for *boil* but not for *stir*.

A 'valid reasoning' is a generalization of entailment that involves more sentences than two. If someone accepts (7) and (8), they may conclude correctly (9):

(7) John sings.

(8) John is a man.

(9) A man sings.

A more intricate example is (Groenendijk and Stokhof, 1982):

(10) John knows whether Mary comes.

(11) Mary comes.

(12) John knows that Mary comes.

Here, one sees that there is a relation between the meaning of the *whether* clause and the *that* clause. It seems that the latter is weaker. However, the relation is more complicated: if one has the negated version (11a), then (12a) follows from (10) and (11a)

(10) John knows whether Mary comes.

(11a) Mary does not come.

(12a) John knows that Mary does not come.

Hence the relation between the *whether* clause and the *that* clause depends on the factual situation.

A special case of entailment is 'synonymy.' Sentences are called synonymous just in case they entail each other. For example, sentences (13) and (14) are synonymous:

(13) John or Mary comes.

(14) John comes or Mary comes.

Another example of synonymy is (Partee and Bach, 1981):

(15) Mary admires herself, and Sue does too.

(16) Mary admires herself, and Sue admires herself.

It may seem that the meaning of the *does too* clause can be found by the substitution of a phrase that occurs elsewhere in the sentence. This is, however, not always the case. It is, for instance, possible to conclude from (17) to (18).

(17) Mary believes that she is ill, and Sue does too.

(18) Mary believes that she is ill, and Sue believes that Mary is ill.

This illustrates the important phenomenon of 'ambiguity.' Sometimes a sentence can be understood in two or more ways corresponding with distinct consequences. From (17), one may conclude either that

(19) Sue believes that Mary is ill.

or that

(20) Sue believes that she (= Sue) is ill.

Another example of ambiguity is (e.g., Janssen, 1983, 1986b):

(21) Ten years ago, John met the president of the USA.

(22) The president of the USA is Bush.

On the one reading of (21), one may conclude that ten years ago John met Mr. Bush. On the other reading, this does not follow since John met the person who was president ten years ago. This ambiguity clearly concerns the functioning of tense operators.

The decision whether a sentence is ambiguous or vague is not always clear. Consider (23):

(23) Two girls are five sandwiches.

One may ask what counts as a source of semantic ambiguity; if it makes a difference whether they shared all five sandwiches; whether the sandwiches were distributed between the girls; or if it makes a

difference whether they ate together or whether each girl ate on her own. Maybe the issue would be more exciting if the sentence was *Two girls shot five men* and one had to judge the girls. Verkuyl and Van der Does (1996) argue that (23) has one meaning, whereas they refer to other authors who argue for a fourfold or even ninefold ambiguity.

So far, only examples of relations between declarative sentences have been cited. Other types of sentences take part in 'other semantic relations,' as between the questions (24) and (25):

(24) Which girls came to the party?

(25) Did Mary come to the party?

In this example, there is nothing like the acceptance of a premise or of a conclusion. Nevertheless, there is a relation: every answer to the first implies an answer to the second question. The meanings assigned to these questions should account for this (Groenendijk and Stokhof, 1989).

Sequences of sentences likewise have logical properties. Consider (26) and (27).

(26) A man walks in the park. He whistles.

(27) A man in the park whistles.

This example puts a requirement on the treatment of texts. The meaning of the two sentences together should be equivalent to the meaning of the single sentence.

All examples discussed in this section have the common feature that they do not depend on specific details of the meanings of the words involved (except for logically crucial words such as *not* or *and*). It is, for example, possible to account for the inference from (1) *Mary is singing and dancing* to (2) *Mary is dancing* without describing the differences between *dancing, jogging*, and *walking*. Each of the examples can be replaced by another which exhibits the same pattern but uses other words. The examples illustrate that in Montague semantics one is mainly interested in structural aspects of the semantic relations between sentences, that is, in the systematic aspects of meaning. The formalization of what meanings are, does not need to go further than is required for an adequate account of these structural aspects.

The Compositional Approach

The most salient aspect of Montague semantics is the systematic way in which natural language expressions are connected with their respective meanings. This relation is characterized by the principle of compositionality of meaning. Such a principle can, in several formulations, be found in many disciplines that deal with semantics, such as linguistics, philosophy, and computer science. In philosophy of language, it has a long tradition and is often called 'Frege's principle.' The version of this principle that describes the method of Montague grammar most explicitly is (Partee *et al.*, 1990: 318):

> The meaning of a compound expression is a function of the meanings of its parts and of the syntactic rules by which they are combined.

The formulation of the principle contains several vague terms, and a proper application of the principle requires a more formal interpretation (for a discussion of the principle, its formalization, consequences, and its status, *see* **Compositionality, Aspects of**). The main points of its formalization are summarized here.

The syntax of the grammar consists of rules which express how new expressions can be formed from already available ones. The rules are, therefore, operations which act on inputs and yield an output. If an expression E is the output of the application of a rule R, then the inputs that form E are defined as being the parts of E in that derivation. The semantic component is organized in a parallel way: there are semantic rules that operate on input meanings and yield an output meaning. The crucial factor for obeying compositionality is that there is a strict correspondence between syntax and semantics. For each syntactic rule, there should be a corresponding semantic rule expressing the semantic effect of that syntactic rule. Compositionality is taken to be not an empirically verifiable property of natural language but a methodological principle: it constrains the organization of the grammar.

Consider example (28):

(28) Penguins do not fly.

A very simple grammar will be considered, naively as regards its meaning. For example, it will be assumed that the sentence says something about all penguins, whereas plurals without article usually have a more subtle meaning. The intention of this example is, however, only to illustrate the *method* of compositionality.

Suppose the grammar has as basic expressions the plural noun phrase *penguins* and the verb *fly*. A rule (say R1) forms the verb phrase *do not fly* from this verb. Furthermore, there is a rule (R2) combining a noun phrase with a verb phrase to form a sentence, by concatenating them and performing the required changes in the verb phrase for agreement and similar trimmings. Then sentence (28) has, according to this grammar, two parts: *penguins* and *do not fly*, and the latter phrase has in turn one part: *fly*.

Figure 1 The derivation tree of 'Penguins do not fly.'

This derivation might be represented in the form of a tree, as in Figure 1. Note that this tree does not depict the constituent structure of the sentence; for example, there are no separate nodes for *do* and *not*. The tree shows how the sentence is formed; it is a construction tree or derivation tree. There is no *a priori* reason why the derivation would be identical to the constituent structure of the result (one might impose this as an additional requirement).

Of course, there might be good arguments for preferring a different grammar. Thus, one might construct (28) out of the positive sentence *Penguins fly*, or, alternatively, from *penguins, fly*, and *not*. In the former case the rule has one part, and in the latter case three parts. Compositionality as such provides no criterion for such issues. The best choice is probably to be discovered by considering more examples and larger fragments.

The principle of compositionality states that the meaning of the sentence is a function of the meanings of its parts, hence (according to the given grammar) of *penguins* and *do not fly*. Of course, the meaning of the latter is, in turn, a function of the meaning of its part *fly*. So, in the end, the meanings of the basic expressions are attained. Adopting for the moment a very simple conception of meaning that will be revised in the next section, one can take the meaning of *fly* to be the set of individuals who fly, and the meaning of *penguins* to be the set of individuals who are penguins.

According to the rules, the verb phrase *do not fly* has only *fly* as a part, and therefore the meaning of this verb phrase has to be formed out of the meaning of *fly*. So there has to be a semantic operation that expresses the meaning of negating a verb. For the moment, the meaning of *do not fly* is, in analogy of that of *fly*, the set of individuals who do not *fly*. The operation that forms this meaning from the meaning of *fly* is the formation of a set complement. In line with the above assumptions about meaning, one may say that the sentence means that the set of penguins is included in the set of nonflying individuals. This meaning is to be obtained from the meanings of its parts: from the set of penguins, and from the set of individuals who do not fly. This can indeed be done.

The situation is as follows. Two syntactic rules (R1 and R2) are each accompanied by a semantic interpretation (M1 and M2, respectively):

R1: negating a verb
M1: complement formation
R2: concatenating a noun phrase with a verb phrase, performing agreement changes
M2: set inclusion

In this section, the method of compositionality has been exemplified. The crucial aspect is the correspondence between syntax and semantics. One might change the concept of meaning used above, or change the syntax used; but as long as the correspondence remains infact, the grammar can be seen as an instance of Montague grammar. This characterization of Montague's method is given in a formal mathematical terminology in his paper 'Universal grammar' (Montague, 1970b).

Interpretation in a Model

In Montague grammar, as well as in all other formal theories of semantics, the natural language expressions are interpreted in a class of abstract models. For example, a name like *John* is associated with an individual in such models, and an adjective like *brave* is a property. Each model is constructed out of a number of basic sets by means of standard constructions, and the result can be restricted by 'meaning postulates.' The most characteristic feature of the models in Montague grammar is the distinction made between the 'extension' of an expression and its 'intension,' a distinction that will be the topic of the next section. In the present section, the status of the model and its connection with natural language will be considered.

The model in which humans interpret natural languages has, of course, a certain resemblance to the real world, but it should not be conceived of as a model of the real world. There are two differences. First, in language, one speaks not only about the real world, past, present, and future, but also about situations that might be the case. Even though unicorns do not exist, one can speak about them, and the sentences used have semantic properties that should be dealt with. The model thus embraces much more than reality.

Second, as far as the model is connected with reality, it is a model of how natural language 'conceives' of it. This conception might be different from the real situation. Examples are mass nouns like *water* or *air*. In natural language, they are used in a different way from count nouns such as *chair* or *flower*. The mass noun *water* is used as if every part of a quantity of water is again water; as if it had no minimal parts. The same holds for *air*. Although in reality water has minimal molecules, and air is a mixture, the model will not reflect that fact (Pelletier and Schubert, 2003).

Although the model does not reflect reality, one can be interested in the relation which it has with reality. Examples are the relation between *blue* and the frequencies of light, or the number of exceptions accepted when it is said that *all ravens are black*. This kind of research is rare in Montague grammar, however, because it amounts to the analysis of specific words, whereas in Montague grammar one is mainly interested in the more structural aspects of the semantics of natural language.

The model, not being a model of reality, might be regarded as a model of how the human mind conceives reality. Although psychological reality is not one of the claims of Montague grammar (it is so in some other theories), the issue has received some attention (e.g., Dowty, 1979: ch. 8).

The connection between natural language and the model can be made in two ways. One method, the direct one, was followed in the section 'The Compositional Approach': for a word, some element (set, function) in the model is given as the meaning of that word, and for each syntactic rule a corresponding meaning operation is given. This method is used in Montague's first publication (Montague, 1970a), and in a few other publications as well (e.g., Keenan and Faltz, 1985). The other method is the indirect one: natural language is translated into some logical language, which is interpreted in a model. If this translation is compositional, and the interpretation of the logical language is compositional, then the combination of the two processes is a compositional process of meaning assignment. Care has to be taken that the logic is used as an auxiliary language only, so that this intermediate language can in principle be eliminated. This implies that every operation that is performed in the logic should have an interpretation in the model. This indirect method is the standard method in Montague grammar; usually, (variants of) intensional logic are used as the intermediate language.

Extension and Intension

An important decision concerns the question of how to model meaning. Previously, the meaning of *penguins* was defined as the set of penguins, and of *fly* as the set of flying individuals. Applying the same approach to *the president of the USA* [example (22)], would yield as meaning the individual Bush, and applied to *unicorn* (assuming there are none) the empty set. This approach would, however, give results that are intuitively incorrect. It would have the consequence that in case neither unicorns nor centaurs exist, the meaning of *unicorn* would be equal to the meaning of *centaur*. As for *the president of the USA*, it would have the undesirable consequence that its meaning changes after each election. Examples like these have led to the distinction between two kinds of interpretation: extension and intension.

At the time of writing, the president of the USA is Mr Bush, but at other moments in time a different person will be president, and in another course of events Mr Bush could have lost the election and Mr Kerry would be president. The model in which natural language is interpreted has components dealing with this. It has a collection of time points for dealing with changes in the course of time, and it has a collection of so-called 'possible worlds.' These possible worlds represent the possibility that Kerry has won. They also represent the possibility that unicorns exist. Intensions are functions with possible worlds and time points as domain. The intension of *the president of the USA* is a function from time points and possible worlds that yields an individual (the president at that moment in that possible world), and the intension of *unicorn* is the function that yields for each possible world and time point a set of individuals (the unicorns). The extension of an expression is the value of the intension function with respect to a given world and time point, for example, the moment now in the actual world. Then the extension of *the president* is the president now (Mr Bush), and the corresponding extension of *unicorn* is the actual set of unicorns. The extension of a sentence is traditionally identified with its truth value. Thus, the extension of *John kisses Mary* is true just in case John kisses Mary. The intension is the function which says, for each possible world, in which moments John kisses Mary.

Since there are possible worlds in which there are unicorns but no centaurs, the words *unicorn* and *centaur* have different intensions. As a consequence, sentences (29) and (30) will have different intensions too.

(29) John seeks a unicorn.

(30) John seeks a centaur.

Thus, using intensions, the nonsynonymy of (29) and (30) can be accounted for. For this purpose, no further information concerning relations between different possible worlds is needed, nor any information concerning relations between time points. This holds for all examples mentioned in the section 'Aims,' and therefore the set of possible worlds and the set of time points are usually introduced as just sets without further specification. This is, however, not always sufficient.

If one is interested in tense phenomena in natural language, then more has to be said about the

moments of time, for example that they are linearly ordered, and whether they are indivisible points or intervals with a duration. If one is interested in causatives (*John broke the glass*) or counterfactuals (*If Mary did not come, John would fly*), then the set of possible worlds needs more structure. For dealing with these phenomena, it is crucial to know how the world was just before the breaking of the glass, or which world resembles the present one except for the coming of Mary.

The above discussion shows that the formalization of the intuitive notion of meaning as intension is much better than as extension. However, intensions only deal with those aspects of meaning that have to do with truth and denotation, and neglect aspects such as style, new information versus old information, etc. Therefore, they can only be regarded as a restricted approximation of meaning. Even accepting this limitation, however, intensions are still not completely satisfactory. At important shortcoming concerns tautologies. Consider (31):

(31) Bill comes or does not come.

The intension of this sentence is the function that always yields 'true.' Hence (32) and (33) have the same intension.

(32) John comes.

(33) John comes and Bill comes or does not come.

This causes problems with embedded clauses. Sentences (34) and (35) will have the same intension, whereas they should not be equivalent since Mary's beliefs in (34) do not concern Bill; she may not even know about his existence:

(34) Mary believes that John comes.

(35) Mary believes that John comes and that Bill comes or does not come.

The conclusion is that intensions are not fine-grained enough to distinguish the meanings of sentences like (34) and (35). Several improvements have been proposed, such as structured intensions (Lewis, 1970), and an approach based on partial functions (Muskens, 1989).

A Small Fragment

This section presents as examples three sentences and their treatment. The treatment given in Montague (1973) will be followed, except for one detail (see next section). In the course of the presentation, some important features of intensional logic will be explained.

The sentences are:

(36a) John walks.

(37a) A man walks.

(38a) Every man walks.

These sentences are very simple, and it is easy to present their interpretation in traditional predicate logic:

(36b) $\text{walk}(\text{john})$

(37b) $\exists x[\text{man}(x) \wedge \text{walk}(x)]$

(38b) $\forall x[\text{man}(x) \rightarrow \text{walk}(x)]$

One immediately sees that these three sentences are syntactically much alike (a subject and a verb), but the formulas in predicate logic are rather different: two with a quantifier (different ones!), and in each case another main operator ($\rightarrow$, $\wedge$, and predicate application). What makes it interesting to present these examples here is not the meaning assigned to them, but the fact that these very different meanings can be derived compositionally from the corresponding sentences.

All three sentences are built from a singular noun phrase and the verb *walks*, and for this reason one can design a single syntactic rule that combines a noun phrase and a verb. Since in Montague grammar there is a correspondence between syntactic rules and semantic rules, one also has to design a rule that combines the meaning of the verb with the meaning of the noun phrase. This in turn requires that there be meanings for verbs and for noun phrases. These meanings will be discussed first, then the semantic rule will be designed.

As explained in the previous section, predicates are given intensions as meanings: functions from possible worlds and moments of time to sets of individuals. Thus, the intension, or meaning, of the verb *walk* is a function from possible worlds and moments of time to sets: for each possible world and each moment of time, there is a set (possibly empty) of individuals who walk. Such an intension is called a 'property.' For the noun phrases, it is more difficult to select a format that allows these meanings to be rendered uniformly. In order to keep the calculus going in a maximally uniform way, all noun phrase meanings should preferably be of the same type. This requirement is easily seen to be nontrivial, as, for example, the expression *every man* extends over sets of possibly many individuals, where *John* seems to refer to one individual only.

Montague proposed (1973) to model the meaning of a noun phrase as a set ('bundle') of properties. An

individual is, in this approach, characterized by the set of all its properties. This is possible since no two individuals share all their properties at the same time, if only because the two cannot be at the same place at the same time. This approach permits generalization over all noun phrases referring to (sets of) individuals (see also Lewis, 1970).

Meanings of linguistic expressions (functions from world–time pairs to specific world extensions) are denoted by formulas in the language of intensional logic. The meaning of *John* will be denoted by:

(39) $\lambda P[^{\vee}P(\text{john})]$

To explain this formula, the variable

(40) P

is a variable over properties of individuals: P may be replaced, for example, by the property 'walking.' The expression

(41) $^{\vee}P$

denotes the extension of the property expressed by any predicate P in any given world at a given moment of time. Thus, for the actual world now.

(42) $^{\vee}P(\text{john})$

is true if the predicate $^{\vee}P$ holds for John now in this world, and false otherwise. Any property denoted by P can be abstracted by means of the lambda operator: λP. Lambda abstraction of (42) gives:

(43) $\lambda P[^{\vee}P(\text{john})]$

which is the same as (39) above. This expression denotes a function which says, for any property α, given a world–time pair <w, t>, whether John belongs to the extension of that property in <w, t>. Let this function be called X_j. Some properties of this function will now be investigated.

According to the definition of X_j:

$X_j(\alpha)$ is true if and only if α now holds for the individual John, i.e., $^{\vee}\alpha$ (*john*) is true, and false otherwise (I)

X_j is, therefore, the characteristic function of the set of properties that can be predicated of John. As usual in logic, this characteristic function can be identified with the set of properties that John has X_j can therefore be seen as a formalization of the idea that the meaning of *John* is a set of properties.

This function X_j can be evaluated with as argument the property of being a man, that is, the function that yields for each index (i.e., for each world and time) the extension of the predicate *man*. The notation for this argument is:

(44) $^{\wedge}\text{man}$

The symbol $^{\wedge}$ translates the predicate *man* into the language of intensional logic, where $^{\wedge}$*man* denotes the intension associated with *man*. X_j is now applied to this argument to obtain, using result (I).

$X_j(^{\wedge}man)$ is true if and only if $^{\wedge}man$ now holds for the individual John, i.e., if and only if $^{\vee\wedge}man(john)$ is true, and false otherwise (II)

In the expression $X_j(^{\wedge}\text{man})$, X_j can be replaced by its original definition (viz. (43)). Then, (45) is obtained.

(45) $\lambda P[^{\vee}P(\text{john})]\ (^{\wedge}\text{man})$

Result (II) now states that this is equivalent with

(46) $^{\vee\wedge}\text{man(john)}$.

Thus, it has been shown, using semantic considerations, that it is allowed to substitute the argument $^{\wedge}$*man* for the variable P, an operation known as 'lambda conversion.' According to the definitions given with (41) and (44), $^{\vee\wedge}$*man* denotes the present value of the property of being a man. Hence (46) and (45) are equivalent with (47)

(47) man(john)

Summarizing, the variable P in (45) has been replaced with the property $^{\wedge}$*man*, which is in the range of P, and $^{\vee\wedge}$*man* has been reduced to just *man*. As the operations concerned are admissible independently of the particular choice of the predicate *man*, the procedure can be generalized to all predicates of the same class (type).

To revert to the treatment of the simple sentence *John walks*, the syntax has, as stipulated earlier, a rule that combines a noun phrase with a verb to form a sentence. What is still needed is a semantic operation that matches the syntactic rule with its semantic consequences. The operation that does this is so-called 'function application': one of the two syntactic constituents acts as a function, while the other acts as argument (input). In this case, the verb meaning is allowed to act as the argument, and the noun phrase meaning as the function. The result of function application, in this case, is a function from world–time pairs to truth-values, or the set of world–time pairs where John walks.

According to the rule just given, the meaning of *John walks* is found by application of the meaning of *John*, that is (43), to the meaning of *walk*. This is denoted by:

(48) $\lambda P[^{\vee}P(\text{john})](^{\wedge}\text{walk})$

This, as seen above, can be reduced, in two steps, to:

(49) walk(john)

which now gives the meaning representation aimed at.

For the other sentences, one proceeds analogously. The noun phrase *a man* is likewise translated as a set of properties:

(50) $\lambda P[\exists x[man(x) \wedge {}^{\vee}P(x)]]$

This denotes the characteristic function of the set of properties such that for each property in the set there is a man that has that property. The sentence *A man walks* is then represented as:

(51) $\lambda P[\exists x[man(x) \wedge {}^{\vee}P(x)]]({}^{\wedge}walk)$

which reduces to:

(52) $\exists x[man(x) \wedge walk(x)]$

Analogously, every man walks is represented as.

(53) $\lambda P[\forall x[man(x) \rightarrow {}^{\vee}P(john)]]({}^{\wedge}walk)$

or equivalently

(54) $\forall x[man(x) \rightarrow walk(x)]$

This treatment illustrates some of the power of lambda abstraction and lambda conversion. The meaning of the verb is 'plugged into' the meaning of the noun phrase in the right position. Lambda calculus is frequently used in Montague grammar. Without the lambda operator, it would be impossible to maintain compositionality. Impressed by the power of lambdas, Barbara Partee once said: 'Lambdas really changed my life.' What has been, in the end, obtained as meaning representations for the three sentences discussed is nothing more than the formulas usually associated with them in elementary logic courses. There, however, they are found on intuitive grounds, whereas in Montague grammar they are the result of a formal system which relates syntax and semantics in a systematic way.

Some PTQ Phenomena

Montague worked out his ideas in a number of papers, the most influential of which is 'The proper treatment of quantification in ordinary English,' henceforth PTQ (Montague, 1973). This article deals with some semantic phenomena, all connected with quantifiers. Three such phenomena will be discussed here: identity and scope ambiguities (both presented here because they have been the subject of a great deal of discussion since the publication of PTQ), and the 'de dicto–de re' ambiguity, central to Montague grammar, and the origin of its trade mark, the unicorn.

The first phenomenon concerns problems with identity. Consider:

(55) The price of one barrel is $1.00.

(56) The price of one barrel is rising.

(57) $1.00 is rising.

It is obvious that (57) must not be allowed to follow logically from (55) and (56), as $1.00 will remain $1.00 and will neither rise nor fall. The same phenomenon occurs with temperatures, names, telephone numbers, percentages, and in general with all nouns which may denote values. The PTQ treatment of such cases is as follows. Prices, numbers, etc. are treated as basic entities, just as persons and objects. The expression *the price of one barrel* is semantically a function that assigns to each world–time index a particular price. Such a function is called an 'individual concept.' In (55) an assertion is made about the present value of this function, but in (56) an assertion is made about a property of the function. Thus, the expression *the price of one barrel* is considered ambiguous between a value reading and a function reading. The difference in readings blocks the false conclusion (57).

In spite of criticisms, mainly related to the treatment of such nouns as basic entities (e.g., Bennett, 1976), the notion of individual concepts also seems useful to account for cases like the following (Janssen, 1984).

(58) The treasurer of the charity organization is the chairman of the hospital board.

(59) The treasurer of the charity organization has resigned.

(60) The chairman of the hospital board has resigned.

Here, substitution *salva veritate* of terms under an identity statement seems to be running into difficulty. Again, one can say that (58) is a statement about the identity of the values of two different functions at a given world–time index, whereas (59) is a statement about the function (in Frege's terms, about the *Wertverlauf*). Hence the nonvalidity of (60) as a conclusion is explained.

The second phenomenon is scope ambiguity. Consider

(61) Every man loves a woman.

In PTQ, this sentence is considered to be ambiguous (though many linguists would disagree; see below). In the one reading, one particular woman is loved by all men, and in the other every man has at least one woman whom he loves. The first reading is given in

(62), and is called the specific reading, or the wide scope reading for *a woman*. The second reading is given in (63); it is called the 'narrow scope reading.'

(62) $\exists x[\text{woman}(x) \wedge \forall y[\text{man}(y) \rightarrow \text{love}(y, x)]]$

(63) $\forall y[\text{man}(y) \rightarrow [\exists x\ \text{woman}(x) \wedge \text{love}(y, x)]]$

Many linguists consider (61) to be unambiguous. Well-known is the principle which states that the most plausible reading is given by the surface order of the quantified NPs (and of the negation). Following this principle, (61) has only one reading, viz. (63). Note that the reading expressed by (62) is a special case of (63). The principle has not remained unchallenged. Witness (64), where the most plausible reading is not given by the surface order.

At the finish, a medal is available for all participants in the race.

There are other linguistic theories which also assign one reading to (61). But whether (61), the PTQ example, really is ambiguous is less relevant as long as there are sentences that do show scope ambiguities, which seems beyond doubt. For instance, previously an example involving tense was given (*Ten years ago, John met the president*). The machinery of PTQ for dealing with scope ambiguities is presented below.

Since the scope ambiguity does not seem to have a lexical source, the principle of compositionality of meaning requires the construction of two different derivations for the two readings. In PTQ, this is done as follows. First, the basic sentence (65) is formed, in which neither of the two noun phrases occurs but which contains indexed variables (he_n) instead:

(65) he_1 loves he_2.

Next, noun phrases are substituted for the variables. This can be done in two different orders. The noun phrase that is substituted last gets the widest reading. Thus, the specific reading (wide scope for *a woman*) is obtained from (65) by first forming (66).

(66) Every man loves he_2.

and then

(67) Every man loves a woman.

These rules are called 'quantification rules.' The corresponding semantic rule leads to an interpretation equivalent to that of (62). For the other reading, the reverse order of quantifier substitution is used.

These quantification rules have met with some resistance from linguistic quarters, where they are looked upon as unusual creatures. Other solutions have been attempted, where the disambiguation is not done in the syntax. Cooper (1979) deals with scope phenomena in a separate component, a 'storage' mechanism. Hendriks (1993) uses rules which change the meaning of a noun phrase from a narrow scope reading to a wider scope reading.

The third phenomenon is the ambiguity of 'de dicto' versus 'de re' readings. To see the difference, first consider (68) and (69):

(68) John finds a unicorn.

(69) There is a unicorn that John finds.

Sentence (69) follows from (68). Yet (71) does not follow from (70):

(70) John seeks a unicorn.

(71) There is a unicorn that John seeks.

In fact, (70) is ambiguous between a specific reading in which there is a specific unicorn that John seeks, and an intensional reading where John is said to engage in the activity of seeking a unicorn and nothing is implied about the real existence of such animals. The latter reading is usually called the 'de dicto' reading ('de dicto': Latin for 'about what is said'). The former reading is the 'de re' reading ('de re': Latin for 'about the thing'). The ambiguity is accounted for, in principle, in the following way. In the 'de re' reading, a relation is asserted to hold between two individuals. The 'de dicto' reading establishes a relation between John and the set of properties of a unicorn (i.e., the interpretation of the noun phrase *a unicorn*). Whether this way of analyzing and accounting for the 'de dicto' reading is satisfactory in all respects is a question still widely debated (see e.g., Gamut, 1991).

The two readings of *John seeks a unicorn* are obtained in the following way. For the 'de re' reading, a quantification rule introduces the expression *a unicorn*. And if the expression *a unicorn* is introduced directly, that is, without the intervention of a quantification rule, the result is the 'de dicto' reading. In principle, this method is analogous to the method used to express scope differences. One may, in fact, regard the distinction between 'de dicto' and 'de re' readings as a distinction due to scope differences of the intensional operator *seek*.

Developments

Montague (1973) (henceforth PTQ) signaled the start of a great amount of semantic research. Nowadays there are many linguistic theories that deal in a formal way with semantics, and certainly not all of them obey Montague's compositional framework, but in one respect they are all indebted to him: lambdas are used frequently (see section 'A Small Fragment' for the power of lambdas). This section reviews some

of the developments that have emanated since PTQ and remain more or less within his compositional framework.

In the first period one kept close to the style of PTQ: one widened the original fragment with new phenomena. A characteristic example is the title 'A variation and extension of a Montague fragment of English' (Bennett, 1976). In such articles one finds treatments of relative clauses, passives, scope, control, numbers, plurals, generics, complement structures, and deictic pronouns: most deal with English, some with other languages. For references to these early works see Partee (1976), Gamut (1991), and Dowty *et al.* (1981). Nowadays the habit of providing explicit fragments is abandoned: one focuses on some semantic phenomenon and provides rules for that phenomenon only.

The first broadening of the scope of Montague semantics was toward lexical semantics. In PTQ the words are regarded as basic and remain unanalyzed except for a few logically interesting words such as the verb *be*: often, however, it is linguistically interesting to carry the analysis of words further. Examples (5) and (6) featured the word *cool*, which can be an adjective, an intransitive verb phrase, and a causative verb, with related meanings. Such lexical analyses are given in Dowty (1979).

Montague used a primitive kind of syntax. On the one hand, this appears from the fact that the syntactic rules are not subject to any formal restriction; on the other hand, from the absence of grammatical features and a well-motivated constituent structure and grammatical functions. Soon after the publication of PTQ, proposals were made to incorporate syntactic know-how as developed in transformational grammar into Montague grammar (see, e.g., Partee, 1975 and Dowty, 1982). Partee's ideas for combining Montague grammar with transformational grammar are worked out in the large grammar used in the machine translation project Rosetta (Rosetta, 1994).

Since the earliest years of Montague semantics there have been attempts to make the syntactic rules as restricted as possible by using only concatenation rules. As a consequence, the constituent structure of the natural language expression becomes isomorphic to its compositional analysis. Because of this feature, such approaches are said to obey 'surface compositionality.' The approach leads to (variants of) categorical grammar. An early advocate of this approach was Bach (see, e.g., Oehrle *et al.*, 1988); a recent monograph within the framework of Montague is Morill (1994). Surface compositionality requires a treatment of scope phenomena different than Montague's. An important idea is the use of type shifting rules: such rules make the relation between a word and its semantic type less rigid than in PTQ, and therefore this approach is called 'flexible Montague grammar.' The method is useful for several phenomena (including scope); see Partee and Rooth (1983), Hendriks (1993), and Groenendijk and Stokhof (1989).

As explained previously, noun phrases are treated in PTQ as sets of properties. Consequently the determiner 'every' is a function from sets to sets: it can be conceived of as a relation between two sets (e.g., in 'Every man dances' as a relation between 'man' and 'dance'). This abstract analysis of noun phrases opened the way to a new field: the theory of 'generalized quantifiers,' in which many phenomena concerning noun phrases are studied. The pioneering article is Barwise and Cooper (1981); monographs are Keenan and Faltz (1985) and Winter (2001), (*see* **Quantifiers: Semantics**).

The largest linguistic units analyzed in PTQ are sentences. The task of extending Montague's method to discourses looked unrewarding at first, particularly in view of cross-sentential anaphora phenomena. The first step from sentence to discourse (Kamp, 1981) was, on certain details, not compositional. Later a compositional treatment was given (Groenendijk and Stokhof, 1991). The key feature of their approach was that the meaning of a sentence is not a truth value, but its information change potential: a function that changes the information state. This led to dynamic semantics, an approach in which several other 'information' phenomena can be analyzed (*see* **Dynamic Semantics**).

Also, the ontology used by Montague has been challenged. His ontology was based upon a hierarchy of typed sets, but several phenomena suggest a change. Mass nouns seem to ask for sets that do not have elements (Pelletier and Schubert, 2004). Nominalizations (as in *I love loving*) seem to ask for an alternative in which functions can have themselves as arguments; this leads to property theory (see, e.g., Chierchia, 1982). Perception verbs challenge the basic role of possible worlds. They are abandoned by Barwise and Perry (1983), who replace them by 'situations,' but a classical model with partial functions can also be used (Muskens, 1989). PTQ deals with only one type of language utterances, declarative sentences, and one may think that other utterances require other types. But questions can be treated without a new ontology, as is shown by the work on the semanties of questions and wh-complements (Groenendijk and Stokhof, 1982, 1989).

Further Reading

A well-known introduction to Montague grammar (especially written for linguists) is Dowty *et al.*

(1981). An introduction with much attention paid to logical and philosophical motivation is Gamut (1991). An introductory article on 'Universal grammar' (Montague, 1970b) is Halvorsen and Ladusaw (1979), its mathematical background is investigated in Janssen (1986a) and discussed in Janssen (1997). Publications on Montague grammar often appear in *Linguistics and Philosophy*. Many references are given in Partee and Hendriks (1997), recent collections of papers about Montague grammar are Partee (2004), and Portner and Partee (2002).

Montague, Richard (1931–1971)

B Partee, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Richard Montague was a logician and philosopher whose seminal works on language (Montague, 1970a, 1970b, 1973) were the basis for the theory known after his death as Montague grammar, one of the main starting points for the field of formal semantics.

Montague was born September 20, 1930 in Stockton, California, and died March 7, 1971 in Los Angeles. At St Mary's High School in Stockton, he studied Latin and Ancient Greek. After a year at Stockton Junior College studying journalism, he entered the University of California, Berkeley in 1948, and studied mathematics, philosophy, and Semitic languages, graduating with an A.B. in philosophy in 1950. He continued graduate work at Berkeley in all three areas, especially with Walter Joseph Fischel in classical Arabic, with Paul Marhenke and Benson Mates in philosophy, and with Alfred Tarski in mathematics and philosophy, receiving an M.A. in mathematics in 1953 and his Ph.D. in philosophy in 1957. Tarski, one of the pioneers, with Frege and Carnap, in the model–theoretic semantics of logic, was Montague's main influence and directed his dissertation (Montague, 1957). Montague taught in the UCLA philosophy department from 1955 until his death.

Montague quickly became a major figure in mathematical logic, with contributions to proof theory, model theory, axiomatic set theory, and recursion theory. He applied logical methods to a number of problems in philosophy, including the philosophy of language, and co-authored a logic textbook (Kalish and Montague, 1964). He directed three UCLA Ph.D. dissertations (Cocchiarella, 1966; Grewe, 1965; Kamp, 1968). A fourth, by Gallin (1972, revised and published as Gallin, 1975), was completed at Berkeley after Montague's death. Michael Bennett would also have been Montague's dissertation student; his dissertation on Montague grammar (Bennett, 1974) was supervised by David Kaplan and Barbara Partee.

Of most significance for linguistics was Montague's work on semantics. Building on his development of a higher-order typed intensional logic with a possible-worlds model–theoretic semantics, and a formal pragmatics incorporating indexical pronouns and tenses (Montague, 1968, 1970c), Montague turned in the late 1960s to the project of 'universal grammar.' For him that meant developing a philosophically satisfactory and logically precise account of syntax, semantics, and pragmatics, encompassing both formal and natural languages. Montague's idea that a natural language like English could be formally described using logicians' techniques was a radical one at the time. Most logicians believed that natural languages were not amenable to precise formalization, while most linguists doubted the appropriateness

Richard Montague was a logician and philosopher whose seminal works on language (Montague, 1970a, 1970b, 1973) were the basis for the theory known after his death as Montague grammar, one of the main starting points for the field of formal semantics.

Montague was born September 20, 1930 in Stockton, California, and died March 7, 1971 in Los Angeles. At St Mary's High School in Stockton, he studied Latin and Ancient Greek. After a year at Stockton Junior College studying journalism, he entered the University of California, Berkeley in 1948, and studied mathematics, philosophy, and Semitic languages, graduating with an A.B. in philosophy in 1950. He continued graduate work at Berkeley in all three areas, especially with Walter Joseph Fischel in classical Arabic, with Paul Marhenke and Benson Mates in philosophy, and with Alfred Tarski in mathematics and philosophy, receiving an M.A. in mathematics in 1953 and his Ph.D. in philosophy in 1957. Tarski, one of the pioneers, with Frege and Carnap, in the model–theoretic semantics of logic, was Montague's main influence and directed his dissertation (Montague, 1957). Montague taught in the UCLA philosophy department from 1955 until his death.

Montague quickly became a major figure in mathematical logic, with contributions to proof theory, model theory, axiomatic set theory, and recursion theory. He applied logical methods to a number of problems in philosophy, including the philosophy of language, and co-authored a logic textbook (Kalish and Montague, 1964). He directed three UCLA Ph.D. dissertations (Cocchiarella, 1966; Grewe, 1965; Kamp, 1968). A fourth, by Gallin (1972, revised and published as Gallin, 1975), was completed at Berkeley after Montague's death. Michael Bennett would also have been Montague's dissertation student; his dissertation on Montague grammar (Bennett, 1974) was supervised by David Kaplan and Barbara Partee.

Of most significance for linguistics was Montague's work on semantics. Building on his development of a higher-order typed intensional logic with a possible-worlds model–theoretic semantics, and a formal pragmatics incorporating indexical pronouns and tenses (Montague, 1968, 1970c), Montague turned in the late 1960s to the project of 'universal grammar.' For him that meant developing a philosophically satisfactory and logically precise account of syntax, semantics, and pragmatics, encompassing both formal and natural languages. Montague's idea that a natural language like English could be formally described using logicians' techniques was a radical one at the time. Most logicians believed that natural languages were not amenable to precise formalization, while most linguists doubted the appropriateness

of logicians' approaches to the domain of natural language semantics. At the time of Montague's work, Chomskian generative syntax was well established, and the 'linguistic wars' between generative semantics (George Lakoff, J. R. 'Haj Ross, James McCawky, Paul Postal) and interpretive semantics (Ray Jackendoff, with the support of Chomsky) were in full swing. In introductions of Montague's work to linguists, including Partee, 1973 and 1975, and Thomason's extended introduction to Montague, 1974, it was argued that Montague's work offered the potential to accommodate some of the best aspects of both of the warring approaches, with some added advantages.

It was the short but densely packed paper known as "PTQ" (Montague, 1973) that had the most impact on linguists and on the subsequent development of formal semantics. 'Montague grammar' has often meant PTQ and its extensions by linguists and philosophers in the 1970s and 1980s. But it is the broader algebraic framework of 'Universal grammar' (UG) (Montague, 1970b) that constituted Montague's theory of grammar. Crucial features of that theory included the truth–conditional foundations of semantics, the algebraic interpretation of the principle of compositionality, and the power of a higher-order typed intensional logic.

Before Montague, semanticists focused on the explication of ambiguity, anomaly, and 'semantic relatedness'; data were often subjective and controversial. The introduction of truth–conditions and entailment relations as core data profoundly affected the adequacy criteria for semantics, and led to a great expansion of semantic research. While some cognitively oriented linguists reject the relevance of truth conditions and entailment relations to natural language semantics, many today seek an integration of cognitive and formal perspectives by studying mind–internal intuitions of mind–external relations, such as reference and truth–conditions.

The Fregean principle of compositionality, that the meaning of any complex expression is a function of the meanings of its parts and of the way they are syntactically combined, was central to Montague's theory and remains central in formal semantics. In UG, Montague formalized it as the requirement that there be a homomorphism between a syntactic algebra and a semantic algebra. The nature of the elements of both the syntactic and the semantic algebras is open to variation; what is constrained by compositionality is the relation of the semantics to the syntax.

The richness of Montague's logic was crucial for the possibility of a compositional semantic interpretation of independently motivated syntactic structure. This was well illustrated in PTQ, where a typed higher-order logic with lambda-abstraction made it possible to interpret noun phrases (NPs) like *every man, the man,* and *a man* uniformly as semantic constituents ('generalized quantifiers'), an idea simultaneously advocated by Lewis (1970). PTQ also contained innovative treatments of quantifier scope and binding, intensional transitive verbs, phrasal conjunction, adverbial modification, and more. Montague's type theory introduced to linguists Frege's strategy of taking function–argument application as the basic "semantic glue" for combining meanings, and gave new significance to categorial grammar (Bach *et al.*, 1987).

Montague's logic was an intensional logic, developing Frege's distinction between *sense* and *reference* and Carnap's distinction between *intension* and *extension*, using possible-worlds semantics to treat the phenomenon of referential opacity, pervasive in belief-sentences and many other constructions.

Details of Montague's analyses have in many cases been superseded, but in overall impact, PTQ was as profound for semantics as Chomsky's *Syntactic structures* was for syntax. Bach (1989) summed up their cumulative innovations thus: Chomsky's thesis was that English can be described as a formal system; Montague's thesis was that English can be described as an 'interpreted' formal system.

Feferman and Feferman (2004) offered vivid glimpses into Montague's relation to Tarski, Montague's life (he was an accomplished musician, became wealthy in real estate, and was a member of the homosexual community), and his death, an unsolved murder.

Montanus, Petrus (ca.1594–1638)

J Noordegraaf, Vrije Universiteit, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Petrus Montanus, or Peter Berch, as this pioneer in phonetics was called in Dutch, was born in the city of Delft. He studied theology at Leiden University in the years 1619–1621. Subsequently, he was appointed minister in Nieuwen Hoorn, a village near the city of Den Briel. There he served until his death in 1638. In 1635 he published *Bericht van een nieuwe konst, genaemt De Spreeckonst* ('Instruction in a new art, called the art of pronunciation/speech'), his sole publication.

Montanus' work was intended to be a handbook of phonetics for schoolmasters. It comprises a theory that could in principle be applied to any language

but is demonstrated largely on the basis of contemporary spoken Dutch. Although the influence of tradition is clearly discernible in various issues, Montanus's views on most of them are far superior to those of his predecessors. As Montanus understood that a speech sound is a complex of features, he developed an ingenious system of distinctions and in fact worked with binary oppositions, being keenly aware of the function of speech sounds as phonemes; the setup of his remarkable book is largely dichotomous.

The *Spreeckonst* gives a highly complicated and sophisticated account of the vocal organs and speech in general, restricting itself to a description of the material aspects of speech forms. Among other things, it was on the basis of sonority (the 'Height of Sound') that Montanus developed a table of the distribution of consonants in a syllable. He describes the syllable as a sound-substance and then as a part of a word, dealing with the word, the word group, and the sentence in a similar way.

Following his compatriot, the distinguished mathematician Simon Stevin (1548–1620), who deemed Dutch to be the most appropriate language to express scientific knowledge, Montanus wrote his study in Dutch instead of in Latin or French, thus largely cutting himself off from a wide European audience. It is understandable that he found it easier to devise technical terms in his native language than in Latin, but owing to the complexity of his newly coined terminology his work is hard to read, even for a native speaker. Montanus's book did not go unnoticed and was recognized as an important publication, for example in D. G. Morhof's well-known *Polyhistor* (1688), but in fact it was not studied seriously for centuries and did not influence the course of phonetic studies. Nowadays, however, the *Spreeckonst* is regarded as a unique document in the history of phonetics and phonology.

Montserrat: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Montserrat is an overseas United Kingdom territory in the eastern Caribbean chain of islands. It is one of the Leeward Islands, known fondly as the Emerald Isle of the Caribbean for its lush green vegetation. Its size is expanding as a result of the volcanic activity in the south of the island. According to the artifacts found on the island, which date from about 500 B.C.E. to 500 C.E., the area was populated during this period by the Arawak people. These people were driven out and absorbed by later Carib people, who were also present when Columbus first visited the island in 1493. The island was later colonized by the English and Irish in 1632. Later it changed ownership between France and Britain several times, and finally it was ceded to Great Britain in 1783. Slavery was abolished in 1834. The production of sugar, on which the country's economy was previously based, fell toward the end of the 19th century and was later replaced by cotton.

Montserrat has had internal self-government since 1960. In 1995 the Soufrière Hills Volcano erupted and destroyed most of Montserrat, together with the capital and the main port. A large part of the population was evacuated, and more than half of the land area was rendered uninhabitable. As a result, the island population underwent a 50% drop after

but is demonstrated largely on the basis of contemporary spoken Dutch. As Montanus understood that a speech sound is a complex of features, he developed an ingenious system of distinctions and in fact worked with binary oppositions, being keenly aware of the function of speech sounds as phonemes; the setup of his remarkable book is largely dichotomous.

The *Spreeckonst* gives a highly complicated and sophisticated account of the vocal organs and speech in general, restricting itself to a description of the material aspects of speech forms. Among other things, it was on the basis of sonority (the 'Height of Sound') that Montanus developed a table of the distribution of consonants in a syllable. He describes the syllable as a sound-substance and then as a part of a word, dealing with the word, the word group, and the sentence in a similar way.

Following his compatriot, the distinguished mathematician Simon Stevin (1548–1620), who deemed Dutch to be the most appropriate language to express scientific knowledge, Montanus wrote his study in Dutch instead of in Latin or French, thus largely cutting himself off from a wide European audience. It is understandable that he found it easier to devise technical terms in his native language than in Latin, but owing to the complexity of his newly coined terminology his work is hard to read, even for a native speaker. Montanus's book did not go unnoticed and was recognized as an important publication, for example in D. G. Morhof's well-known *Polyhistor* (1688), but in fact it was not studied seriously for centuries and did not influence the course of phonetic studies. Nowadays, however, the *Spreeckonst* is regarded as a unique document in the history of phonetics and phonology.

Montserrat is an overseas United Kingdom territory in the eastern Caribbean chain of islands. It is one of the Leeward Islands, known fondly as the Emerald Isle of the Caribbean for its lush green vegetation. Its size is expanding as a result of the volcanic activity in the south of the island. According to the artifacts found on the island, which date from about 500 B.C.E. to 500 C.E., the area was populated during this period by the Arawak people. These people were driven out and absorbed by later Carib people, who were also present when Columbus first visited the island in 1493. The island was later colonized by the English and Irish in 1632. Later it changed ownership between France and Britain several times, and finally it was ceded to Great Britain in 1783. Slavery was abolished in 1834. The production of sugar, on which the country's economy was previously based, fell toward the end of the 19th century and was later replaced by cotton.

Montserrat has had internal self-government since 1960. In 1995 the Soufrière Hills Volcano erupted and destroyed most of Montserrat, together with the capital and the main port. A large part of the population was evacuated, and more than half of the land area was rendered uninhabitable. As a result, the island population underwent a 50% drop after

1995. Since then, many of the inhabitants have moved back, leaving the current number of residents at about 9245 (July 2004 estimate), which is close to the number before the eruption of 1995.

The official language of Montserrat is English. Montserrat Creole English (Leeward Caribbean Creole English) is also spoken, which has a great deal in common with other Caribbean English–based creoles. Primary education for children has been compulsory since 1892. The adult literacy rate is 97%.

Mood and Modality in Grammar

Introduction

The study of mood and modality as grammatical categories has been a relatively underresearched area of interest in recent years, though the many volumes and monograph-length works produced in the past 30 years may seem to belie such a statement. Among the principle publications that discuss aspects related to the general field of mood and modality are Lyons (1977), Coates (1983), Palmer (1986), Horn (1989), Traugott (1989), Sweetser (1990), Warner (1993), Bybee *et al.* (1994), and Bybee and Fleischman (1995). More recent and innovative contributions have also come from other grammatical perspectives such as those of Van der Auwera and Plungian (1998), Goossens (2000), Nuyts (2001), Hart (2003), and Facchinetti *et al.* (2003). Although some of this work, especially the later publications, provides a typological viewpoint, what is noticeable about many of the studies listed is an underlying tendency to focus on the modal system of English, or at least to establish English as a benchmark for the comparison of modal systems in other languages. This practice has resulted in a number of terminological problems, as discussed below.

One of the key attractions of research on mood and modality in grammar, as outlined by Plank (1984), is the facility with which the category can serve to exemplify the diachronic processes of language change in general, for example, grammaticalization. Plank's study linked a blossoming area of linguistic endeavor with a field of grammatical study that was, at the time, largely restricted to the straitjacket of philosophical logic. Grammaticalization occurs when lexical items, or even constructions, used in specific discourse environments, may become automated over time to serve a particular grammatical function, or may come to serve a function that is more grammaticalized than previously (Traugott, 1994: 1481), and as a consequence, become more abstract in meaning. For the most part, the explanation of grammaticalization to account for the meaning shifts in modal verbs and other forms of modality has remained relatively unchallenged, though Fischer (2003) noted that another typical consequence of grammaticalization, decrease in the scope of the grammatical function, is not always observable in the grammaticalization of modal verbs. However, scope decrease is not considered to be a universal feature of grammaticalization in other accounts (Tabor and Traugott, 1998).

Definitions and Categories

The use of the term 'mood' in grammar is often held to be somewhat confusing, especially because of its early associations with classical grammar. Allan (2001: 343) noted that the Greek philosopher Protagoras was the first to identify four moods, the optative-subjunctive, the interrogative, the declarative, and the imperative, linking mood with clause type. The use of mood was discussed by Palmer (2003: 2) as a 'subcategory' of a wider, more general area called modality. Palmer (1986) also qualified mood with reference to a grammatical category, in the same way as tense and time are related; in other words, modality is a notional, or semantic, domain, whereas mood is its grammaticalization across languages. (The use of the term grammaticalization by Palmer and Lyons is not intended so much to describe a historical process, but rather to refer to the formalization of a functional category within a language system.) Bybee *et al.* (1994: 181) described mood as the inflectional expression of modality, which they consider to be the grammaticalization of speakers' subjective attitudes and opinions. Lyons (1995: 179) described mood as the result of the grammaticalization of (subjective) modality and "...other kinds of

1995. Since then, many of the inhabitants have moved back, leaving the current number of residents at about 9245 (July 2004 estimate), which is close to the number before the eruption of 1995.

Introduction

The study of mood and modality as grammatical categories has been a relatively underresearched area of interest in recent years, though the many volumes and monograph-length works produced in the past 30 years may seem to belie such a statement. Among the principle publications that discuss aspects related to the general field of mood and modality are Lyons (1977), Coates (1983), Palmer (1986), Horn (1989), Traugott (1989), Sweetser (1990), Warner (1993), Bybee *et al.* (1994), and Bybee and Fleischman (1995). More recent and innovative contributions have also come from other grammatical perspectives such as those of Van der Auwera and Plungian (1998), Goossens (2000), Nuyts (2001), Hart (2003), and Facchinetti *et al.* (2003). Although some of this work, especially the later publications, provides a typological viewpoint, what is noticeable about many of the studies listed is an underlying tendency to focus on the modal system of English, or at least to establish English as a benchmark for the comparison of modal systems in other languages. This practice has resulted in a number of terminological problems, as discussed below.

One of the key attractions of research on mood and modality in grammar, as outlined by Plank (1984), is the facility with which the category can serve to exemplify the diachronic processes of language change in general, for example, grammaticalization. Plank's study linked a blossoming area of linguistic endeavor with a field of grammatical study that was, at the time, largely restricted to the straitjacket of philosophical logic. Grammaticalization occurs when lexical items, or even constructions, used in specific discourse environments, may become automated over time to serve a particular grammatical function, or may come to serve a function that is more grammaticalized than previously (Traugott, 1994: 1481), and as a consequence, become more abstract in meaning. For the most part, the explanation of grammaticalization to account for the meaning shifts in modal verbs and other forms of modality has remained relatively unchallenged, though Fischer (2003) noted that another typical consequence of grammaticalization, decrease in the scope of the grammatical function, is not always observable in the grammaticalization of modal verbs. However, scope decrease is not considered to be a universal feature of grammaticalization in other accounts (Tabor and Traugott, 1998).

Definitions and Categories

The use of the term 'mood' in grammar is often held to be somewhat confusing, especially because of its early associations with classical grammar. Allan (2001: 343) noted that the Greek philosopher Protagoras was the first to identify four moods, the optative-subjunctive, the interrogative, the declarative, and the imperative, linking mood with clause type. The use of mood was discussed by Palmer (2003: 2) as a 'subcategory' of a wider, more general area called modality. Palmer (1986) also qualified mood with reference to a grammatical category, in the same way as tense and time are related; in other words, modality is a notional, or semantic, domain, whereas mood is its grammaticalization across languages. (The use of the term grammaticalization by Palmer and Lyons is not intended so much to describe a historical process, but rather to refer to the formalization of a functional category within a language system.) Bybee *et al.* (1994: 181) described mood as the inflectional expression of modality, which they consider to be the grammaticalization of speakers' subjective attitudes and opinions. Lyons (1995: 179) described mood as the result of the grammaticalization of (subjective) modality and "...other kinds of

expressive meaning, including some part of what is nowadays commonly referred to as illocutionary force." He went on to stress that the modal verbs of English have, for the most part, assumed the former functions of the Old English subjunctive (the only grammaticalized mood in English), which, arguably, has become reduced, at least in form, to a few isolated, frozen expressions (*If I* ***were*** *you . . .*) and to variable use, for example, in the complements of noun clauses (*She emphasized that the old system* ***be*** *maintained*). In languages such as Spanish and Italian, the subjunctive is still alive and well, though there is a system of modal auxiliary verbs as well.

Allan (2001), following Protagoras in the 4th century B.C., and Palmer (1986) and Lyons (1977), among others, also described mood as a clause type, expressing the primary illocutionary force of an utterance, for example, in making statements, questions, imperatives, and wishes. In using such a definition, he was also comparing the notion of mood, as did Lyons (1977), to that of a speech act (see Searle, 1979). Palmer (1986) was more reserved in involving modality with the theory of speech acts, though he concedes that imperatives, described by Searle as directives, are important in any discussion of deontic modality. In the fact that there is no unique grammatical marker for marking the changes in illocutionary force of utterances (with the exception of the expression of wishes, which are often hypothetical and thus marked with modal auxiliaries or hypothetical past verb tense), it makes little difference whether the definition of mood (in English) describes its formal representation or the clausal environment in which it is found; however, it could be suggested that to use the term to describe the latter is to use an extended definition of the meaning of mood, at least as far as English is concerned. Thus, mood has been described both as the inflectional representation of modality and as the clause type in which modal inflection may appear (in some languages).

All such discussion is futile without a sufficiently comprehensive definition of modality itself. Palmer (2003: 6), dismissing logical, truth-conditional notions of modality relating to factuality or non-factuality, discusses modality as reflected mainly by the presence or absence of assertion in the intended illocution. Lyons (1995: 253–254) discussed speaker commitment, rather than assertion, in defining modality, thus allowing for the fact that even in uttering a declarative statement, the speaker is making a commitment to the truth of that statement. However, there is still conflict with a definition that describes modality in terms of the absence of assertion in the illocution. Palmer's (1986) suggestion, therefore, was that the domain of modality must include the unmarked oppositions and that there exist languages in which a declarative statement cannot be made without some form of modal marking, if only to describe the source of evidence available (as in Tuyuca (Tucanoan)); e.g., visual evidence presents the statement as the strongest with regard to factuality. The definition of modality must include languages in which reference to the factuality of a situation cannot be distinguished from other factors such as reference to distance and perception, providing the speaker's empirical justification for making the statement, all of which can be modalized across languages and not necessarily in the verbal system (e.g., in the examples of Pilagá (Mataco-Guaicuru) noted by Bybee (1998: 265)). Notions of objective factuality, therefore, cannot always be divorced from those of speaker commitment to factuality.

Chung and Timberlake (1985: 241) believed that languages that express modality in terms of mood distinctions such as indicative vs. subjunctive, or optative, as in Attic Greek, are placing finer distinctions on the basic notions available in which modality is the semantic domain expressed in grammar, distinguishing between actual and nonactual events. The evaluation of such events as actual or non-actual, though, is a language-specific matter and there is no way of predicting where such divisions may fall from one language to the next. For example, in some languages, there is no marked distinction between potential and hypothetical or potential and future (Chung and Timberlake, 1985: 243). The typological study of modality involves a much more flexible definition of a semantic domain, which in some languages has reference to actuality versus non-actuality and in others may have reference merely to actuality versus the realm of thought, e.g., for Central Pomo (Hokan), and for Amele (Trans-New Guinea) (Mithun, 1995: 375). Chung and Timberlake referred to the morphological terms 'realis' and 'irrealis' to describe modality from a typological perspective; such terms have also presented their problems, as the functions they serve across a range of languages may vary to the point at which the meaning of the term becomes vague. In their cross-linguistic survey of 76 languages, Bybee *et al.* (1994: 238) declared the term irrealis as not a valid term cross-linguistically to describe modality in the languages concerned. Their frustrations were due partly to the restrictions implied in the use of such terminology to express a binary distinction, something that Bybee herself (1998) criticized later as related to former structuralist ideology and which should be replaced by a description founded in prototype theory. Reaction to the claims of Bybee *et al.* (1994), though, came in a spate of publications that

followed, pressing for some justification for rescuing the terminology or for appropriating to it a more realistic definition. The work of Givón (1994) was one such publication, suggesting that the domain of irrealis interconnected with a range of other grammatically encoded and semantic categories and that as a category it was functionally incoherent and lacked a central meaning. However, some common characteristics did exist, such as the grouping of two broad modal clusters, deontic and epistemic, and the allowance for non-referring noun phrases under their scope (1994: 322). Others followed, e.g., Chafe (1995) in his study of Caddo (Caddoan, Southern), who found that the realis–irrealis distinction was determined by how far people's ideas were judged to be in accord with what they believed to be objective reality (1995: 364). From the discussion that ensued it was clear, as Van der Auwera and Plungian (1998) asserted, that there is no one correct way to define and name modality and the types it represents cross-linguistically.

Modal Verbs

The cross-linguistic tendencies noted by Givón (1994) for a clustering of modal nuances around the two semantic subdomains of deontic and epistemic modality are probably what led some researchers working in the field to conflate the notion of modality as a general term with merely the grammatical realization of deontic and epistemic meanings as expressed through modal auxiliary verbs (e.g., Coates, 1995). With regard to such a paradigm, the main contenders in English include pairs such as *will/would*, *may/might*, *can/could*, *shall/should*, as core forms, and *must* and a variety of peripheral forms such as *be able to*, *be supposed to*, *ought to*, *have to*, *be going to*, *dare*, *and need (to)*. In the case of the pairs, the first of the pairings is the present tense form and the second is the past tense form, described as such on formal grounds only, as the temporal meanings have long disappeared from use in many cases, leaving the past tense form to express, usually, hypothetical meaning. In the case of the peripheral group, described variously as semi-modals, semi-auxiliaries, emerging modals, and so on, recent publications have included Ziegeler (2001, 2003a) for historical studies of *be able to* and *be supposed to*, Visconti (2004) for historical details on *be supposed to*, Nordlinger and Traugott (1997) and Traugott and Dasher (2002) for a study of wide-scope modality with special reference to the history of *ought to*, Fischer (1994) for a study on *have to*, and Krug (2000) for interesting comments on the direction in which *be going to* is going, along with other emerging forms such as *hafta* 'have to', and Duffley (1994) for a comprehensive study of *dare* and *need*. All the core modals are structurally isolable by their identification with other auxiliary forms in English (the NICE properties outlined by Huddleston (1976)) – the capacity for negation, inversion, code, and emphasis, but are distinguished from other auxiliaries by having no third-person singular-*s* suffix, no non-finite forms, and no co-occurrence (in standard English) of two modal forms together (Palmer, 1990: 4). All such properties are brought about by historical development, described below. In the following section, the English modal verbs are discussed with reference to the contemporary distinctions made in much of the recent literature, in order to understand the importance of these cluster types of deontic and epistemic modality. However, it cannot be taken for granted that such terms are sufficient, even to describe the English system.

Classifications

As noted above, Givón (1994) pointed to a common conceptual clustering of modal types around deontic and epistemic senses. Although most accounts agree on the definition of epistemic modality, it is exceedingly difficult to find a suitable, uniformly appropriate term to capture the semantic classification of non-epistemic modal verbs, or even to determine whether all non-epistemic modals can in fact be classed together as one category. Treatments of present-day English modal verbs in more traditional accounts have usually maintained conservative distinctions between root meanings and epistemic meanings, root modals having been associated with meanings such as permission and obligation, but also possibility and necessity, and epistemic meanings being expressive of the degree of confidence held by the speaker in the proposition (Coates, 1995: 55). However, 'root' modality has been criticized as a term to describe such categories (Nuyts, 2001: 25), since it encompasses all the non-epistemic categories, which could mean that modalities originating in the subject are not distinguishable from modalities imposed on the subject by an external force (see below, regarding agent-oriented and speaker-oriented modality). Others have distinguished between categories such as deontic, epistemic, and dynamic modals. Deontic and epistemic modals are said to relate to the speaker, with the former concerning the influence of actions, states, and events (Palmer, 1990: 7). The word *deontic* comes from the Greek meaning 'binding' (Allan, 2001: 359) and thus the meaning of present-day deontic modals usually refers to the permission or prohibition imposed on an actor to

undertake an act, as illustrated in the use of the modals *may* and *can* in (1):

(1) You may not/cannot smoke in this building.

Epistemic modals, on the other hand, are said to refer to the speaker's judgment on the truth of a proposition (Palmer, 1990: 6), the word *epistemic* being derived from the Greek meaning 'knowledge' (Lyons, 1977: 793). Epistemic meanings are illustrated in (2), in which the same modal *may* can be used to express the speaker's evaluation or degree of knowledge of the truth of a situation:

(2) He may/must be smoking outside.

The use of the progressive aspect in (2) clearly indicates a correspondence outlined by McDowell (1991), i.e., the co-occurrence of epistemic modality with perfect or progressive aspect in the complement. Epistemic modality normally co-occurs with stative predicates, and the English perfect and progressive are stative in form, being marked by the auxiliaries *be* and *have*. In (1), on the other hand, the deontic meaning is derived by the co-occurrence of the modal verb with a non-stative predicate, *smoke*.

Because of their relation to the speaker, both deontic and epistemic modal types were considered to be subjective (Palmer, 1990: 7). Subjectivity, in Palmer's account, referred to speaker involvement, whether in terms of influencing a future act or event, as in deontic modality, or in the act of expressing judgment of the truth of a proposition, as in epistemic modality. However, Palmer did not distinguish degrees of strength in the subjectivity of modal utterances; he also did not account for situations in which the deontic modality is imposed by an unexpressed source (not necessarily the speaker) on an inanimate modal verb subject. Such cases have been described as intermediate between prototypical deontic and epistemic functions and are differentiated from deontic modals by the fact that the scope of the modality covers the entire proposition, as for epistemic modals. They are termed 'wide-scope' deontic modals and are associated typically with obligation modal forms such as *ought to* (Nordlinger and Traugott, 1997).

Palmer (1986: 17) made some reference to objective modality, in the fact that a directive such as (1) can have the speaker as source, or some unidentifiable authority whose prohibitions the speaker is simply conveying to another participant. Some modal types are difficult to express non-subjectively, or at least are ambiguous between subjective and objective modality, especially given a first-person subject. Sweetser (1990: 53) illustrated this difference in the use of two lexically differentiated forms of (semi-)modals: *have to* and *need to*:

(3a) I have to stay home, or Mom will get mad at me.

(3b) ? I need to stay home, or Mom will get mad at me.

Have to expresses an externally imposed authority and is therefore less subjective than *need to*, which has a source internal to the subject. Lyons (1977: 800) also discussed subjective and objective modality, maintaining that subjective modality always could be accounted for by the speaker's qualification: an *I-say-so* element in the meaning of the utterance. Objective modality, in addition, had an *it-is-so* element qualifying the utterance, could be quantifiable to a certain degree of probability, and corresponds to the alethic, or aletheutic, modality associated with formal logic. One could hardly associate the meanings of obligation expressed in (1) or (3) with quantifiable degrees of probability, though there is still a clear difference in the degree of subjectivity demonstrated by various deontic modals. Furthermore, it would be difficult to attribute the source of the epistemic modality in (2) to an external participant. Lyons later suggested that the capacity to express objective modality might not be found in some languages and is certainly less commonly encoded in others (1995: 335).

Dynamic modals such as *can* and *will* are associated with the ability and volition of the subject and are suggested to be not modal verbs at all, since they were claimed by Palmer (1990: 7) to express no indication of speaker subjectivity. (In this way, Palmer excluded objective modal meanings from the modal paradigm.) The absence of subjectivity is shown in the following example, in which the modal *can* merely reports on the abilities of the subject (Palmer, 1986: 102):

(4) John can speak Italian.

The only reason for defining *can*, used in such senses as a modal, is based, according to Palmer, on formal grounds. Denison (1993: 293) also made a distinction between deontic and dynamic modality, suggesting that deontic modality is involved with giving permission or obligation imposed performatively by the speaker (as in (1) above) and that dynamic modality lacks a performative sense. The use of the term factive has also been applied to such modals by Li (2003), who considered such modals, especially in past form, as expressive of past facts:

(5) In those days only men could vote in elections. (Quirk *et al.*, 1985: 222)

In (5), the modal *could* has a generic subject and describes a past state of ability or potentiality. Although referring to a statement of fact with regard

to the abilities or capacities of the subject, the inferences of potentiality rather than actuality still influence the modality of the predicate: no specific act of voting is asserted as having taken place. For this reason, such examples are similar to past habituals in that they are modally hybrid, as Givón (1994) suggested, and a 'swing' category between realis (factive) modality and irrealis (non/counter-factive) modality.

Bybee (1985) introduced a single term that cut across the general distinctions of root, some deontic, and dynamic modality described by Coates (1995) and Palmer (1986, 1990). This is agent-oriented modality, which, as its name suggests, describes modality in a notional way by referring to the functions performed. Agent-oriented modality was defined by Bybee *et al.* (1994: 177) as reporting "the existence of internal and external conditions on an agent with respect to the completion of the action expressed in the main predicate." Agent-oriented meanings, then, include obligation, necessity, ability, desire, and root possibility. Bybee *et al.*'s categories also embrace the deontic/dynamic/epistemic distinctions of Palmer (1986) and Denison (1993) noted above; modals such as *can* and *will*, dynamic modals according to Palmer, are listed under agent-oriented modalities as ability and desire, respectively, but deontic modals used in directives, such as *must* and *can* (with a permission sense), are described as speaker-oriented (Bybee *et al.*, 1994: 179). One criticism of the use of such a term, however, might be that it appears to allude to a relational role for the subject of a modal verb; this is clearly not the case, as the expression of modality refers to no committed, agentive act. In fact, Diewald (2001: 32) suggested that the subjects of (deontic) modal verbs are thematically experiencer roles, bearing both goal and source features: the goal is the subject as recipient of the modal directive and the source is the subject as intended actor. For this reason, terms such as 'agent-oriented' might refer instead to situations that are 'potentially agent-oriented', or as Goossens (1987: 28) suggested, describe 'potency', since the agentive act is only implied in the modality.

Other terms that might provide a better insight into the general description of non-epistemic modals could be used to suggest that non-epistemic modality is 'goal-centered' (Frawley, 1992: 425), and involves the commitment of participants other than the speaker, or that it is future-projecting (Bybee *et al.*, 1994: 184), in that the participant is projected to be involved in an activity at some time in the future. In this way, both agent-oriented and speaker-oriented modalities are included and it is clear that any non-epistemic modality will serve a secondary function of expressing future time. Bybee *et al.* specifically excluded the modalities of ability on these grounds – such modalities refer only to a present, on-going state or a state that has been completed at some time. James (1986: 51), however, referred to ability and obligation as precursors or antecedents of action. In one way, then, such modalities have in common the fact that they imply the possibility of future action and for this reason they are lumped together under one semantic umbrella. Perhaps the only difference is that for ability types the modality is only a necessary condition for the subject to attain a future action, whereas permission modals involve an additional qualification – the removal of any social barriers to action (see Talmy, 1985; Sweetser, 1990).

Another categorization is that of semantic maps, as illustrated in van der Auwera and Plungian (1998), in which the domains of deontic and epistemic modality are interlaced with those of participant-internal modality and participant-external modality, with participant-internal modality being illustrated by greater subjectivity, such as in *need to* in (3b), and including Palmer's dynamic modals, whereas participant-external modality could be illustrated by examples such as (3a) as well as (1), having also reference to performative, deontic uses. Van der Auwera and Plungian's account is succinct, dealing strictly with the (logical) modal notions of possibility and necessity, but the mechanisms of change that motivate the pathways shown are not discussed.

Modals of prediction, such as *will/would*, therefore, should not, as they have been in previous studies (e.g., Ziegeler, 1996), be considered on a par semantically or historically with epistemic modals; epistemic uses may be associated with them in some cases, e.g., with present-time reference as in Palmer's (1986) example (*That will be the postman*), but even in combination with stative verb complements, they may be considered in most cases to be non-epistemic (it is quite likely that the use of *will* in *That will be the postman* is pragmatically or meta-textually predictive; it predicts the future actualization of a present assumption: *that is the postman*). According to Palmer (1990: 47), with deontic modality the proposition must always refer to the future, though with epistemic modality the proposition can refer to either the present or the future, e.g., *he may arrive tomorrow* (the speaker's estimations of the truth or the falsity of what it expresses are, nevertheless, grounded in the present time of the utterance). It could be argued then, that, in the case of epistemic future reference, the speaker's assessment of the situation is still deictically located in the present, regardless of the time of the referring event, which in such examples can be marked by the presence of a temporal adverb.

Diachronic Paths of Development

The fact that the same modal verb may be used in either a non-epistemic or an epistemic sense, as shown above in (1) and (2), is reflective of the diachronic route of development demonstrated in the history of the modal forms. All the core modal forms appear to have undergone a similar path of development from main verb to non-epistemic modal, and from non-epistemic to epistemic uses, and there is evidence in a number of historical studies to illustrate such development. One of the earliest studies on the historical priority of non-epistemic over epistemic meanings was Goossens (1982); Shepherd (1982) demonstrated that such a relation could also be captured in the history of a creole language. Plank (1984), as noted above, was an exemplary study of the growing interest in the historical semantic development of the modal verbs at the time, but it was not until Traugott and Dasher's (1989) paper that anything had come near an explanation in terms of pragmatic theory to account for the local, micro-changes that were responsible for the shifts that were apparent from a broader chronological perspective.

Traugott (1989) proposed that the development of epistemic modal meanings in English was mainly the result of the gradual conventionalization and strengthening of pragmatic implicatures; such an explanation has been further developed in a more recent study of the Invited Inferencing Theory of Semantic Change (IITSC) (Traugott and Dasher, 2002). It is a process more closely associated with the effects of metonymic inferencing than with the abrupt shifts of meaning typical of bleaching or metaphor that is the mechanism espoused by Sweetser (1990) to explain the historical development of modal verbs. In a diachronic study of the modals *shall* (**sculan*), *will* (**willan*), and *must* (**motan*), Traugott (1989) traced their development from main verb uses in Old English (600–1125 A.D. in her study), when they often appeared with transitive objects, while at the same time appearing as deontic modals, as in the case of *wolde* (later) 'would', and *wille/wile* 'will' in the following (1989: 37–38), e.g.,

(6) . . . þæt he geornor **wolde** sibbe wi^{I}N hiene þonne gewinn
that he rather wanted peace with him than conflict
'. . . that he wanted peace with him rather than conflict.'
(*Or.* 96.17)

(7) se de wunde lacnigean **wille** giote win on.
he who wounds heal wants pour wine on
'Whoever wants to heal wounds should pour wine on them.'
(*CP* 17 125.11)

Some of the modals already had a use expressing general or typical occurrence, e.g.,

(8) elpendes hyd **wile** drincan wætan
elephant's hide will absorb water
(*Or.* 230.26)
(Traugott, 1989: 39)

Example (8) indicates that predictive inferences were beginning to appear as early as in the Old English period, though Traugott questions the likelihood of a purely deictic future form in Old English. Similarly, *must* was believed not to have developed epistemic meanings expressing the speaker's conclusions and certainty until well after the Old English period. Using an example cited from Visser (1969–1973: 1811), Traugott noted that the first uses of strong epistemic *must* occurring alone without a reinforcing adverb (such as *nedes*) did not appear until the 17th century:

(9) the fruit muste be delicious, the tree being so beautiful
(1623 Middleton, *Spanish Gipsie* 1, i.16)
(Traugott, 1989: 42)

In showing the development of strong epistemic meaning in this way, she illustrated the way in which modal meanings became gradually more subjective over the period of time from Old English to the present day and maintained that such a process did not involve metaphor, as suggested by Sweetser (1990), since it is difficult to understand how a proposition can be obliged to be true on the basis of the obligation contained in the proposition. Old English **motan*, according to Traugott, already was used as a deontic modal of permission (1989: 38); thus, if a speaker says 'You must go', meaning, according to the Old English interpretation of *must*, 'you are allowed to go', and is, according to Traugott, observing Grice's (1975) conversational principle of Relevance and Quantity 2, it can be inferred from the maxim 'say no more than you must' that the addressee is expected to go (Traugott, 1989: 50–51); co-occurrence with an epistemic adverb such as *nedes* is presumed to have contributed to the developing epistemic inferences in the modal as well. This account was later rejected by Bybee *et al.* (1994: 200–201), whose claim of a metaphoric explanation for the development of *must* alone was based on the exclusive temporal domains to which the separate deontic and epistemic uses are restricted. Their argument did not use much analysis of historical data, however, and Goossens (1987) had already revealed that a conceptual overlap between deontic permission (the Old English sense) and epistemic necessity was

possible via the bridging context of deontic necessity in negative environments, with negative permission to do X being semantically equivalent to obligation (social necessity) not to do X (these are the social-manipulative correspondences to the logical equivalences of possibility and necessity). Once the necessity meanings had infiltrated the modal uses via negation, it would only be a matter of time before positive necessity meanings could be generalized from the same source. Goossens (1999, 2000) also illustrated a number of linking stages between deontic and epistemic uses, showing that the transition was not as abrupt as at first perceived and ambiguities were possible, for example, between deontic necessity and inevitability, or weak epistemic necessity (Goossens, 1999: 204):

(10) Wherto and why burieth a man his goodes by his grete avarice, and knoweth wel that nedes **moste** hy dye?
'Why does a man bury possessions because of his great avarice, when he knows well that he must necessarily die?'
(1350–1420. Chaucer, *The Parson's Tale*, 567–571)

Goossens describes this sense as intermediate between deontic necessity and inferable necessity; a similar example is given in Traugott and Dasher (2002: 128) (to whom the gloss in (10) may also be attributed), which reveals true ambiguity between general (or wide-scope) deontic necessity (not necessarily imposed by the speaker) and epistemic readings:

(11) ho-so hath with him godes grace: is dede **mot** need beo guod
'he who has god's grace necessarily is required to be/we can conclude is good'
(c. 1450. *Life of St. Edmund*, p. 440)

Note again the collocation with the adverb *need* meaning, here, 'necessarily', which Traugott and Dasher (2002: 128) considered to have been instrumental in the development of epistemic necessity meanings. Examples such as (11) are evidence that the development from deontic to epistemic was not illustrative of an abrupt leap from one conceptual domain to another as would be associated with metaphor, as metaphor does not allow for such ambiguity; ambiguity, or indeterminacy of meaning, is evidence of the semantic continuity necessary for a metonymic extension, in which the extended meanings are already present as part of the meaning of the source and thus epistemic meanings are already present as latent pragmatic inferences in the earlier root meanings.

Epistemic meanings have been attested for the Old English period, as shown by Warner (1993) in the fact that modals such as *wile* (will), *mæg* (may), *mot* (must), and *sceal* (shall) occur with impersonal subjects, but pre-dating the developmental stages does not affect the fact that the route of development remains the same, with stronger subjective meanings not occurring until after weakly subjective ones and epistemic senses not developing until after deontic or agent-oriented senses. All the evidence leads to a unidirectional path of development for modal verbs from main verb uses to pre-modals, and then from future-projecting, weakly epistemic modals (including habitual and relative future uses) to strong epistemic meanings.

Post-modality

Similar pathways of development have been found in the modal verbs of other languages, as illustrated in, for example, German (Heine, 1995), Mandarin Chinese (Li, 2003), and in most of the 76 languages surveyed by Bybee *et al.* (1994), though there are numerous differences and diversions in the developmental routes and in the source meanings. There are also recent studies that have demonstrated that post-modal stages do exist, e.g., for Swedish *må* 'may' to develop meanings of 'feel' and Standard German and Dutch cognates of the same verb, developing meanings of 'like' (van der Auwera and Plungian, 1998), and a modal verb in Mandarin Chinese, *děi* 'must' has been shown to develop post-modal meanings of lexical necessity from epistemic necessity (Ziegeler, 2003b). Much future work in similar areas may reveal that the development of modal meanings in grammar could be only a participating series of changes in a broader dimension of ever-shifting semantic change, motivated by extensions emerging out of discourse and contextual need. The descriptions and categorizations that we use to explain the cross-linguistic semantic differences of modality in grammar at any one time in their history may reveal only a cross section of a much more enduring process that is likely to extend beyond the boundaries of the grammatical functions to which they are restricted in today's usage.

Mood, Clause Types, and Illocutionary Force

K Allan, Monash University, Victoria, Australia

Sadock and Zwicky (1985) surveyed 35 languages representing a wide range of language families and linguistic areas. They found that every language distinguishes at least three **clause types**: declaratives (1), interrogatives (2), and imperatives (3). It is surely no accident that these are the clause types orthographically marked by '.', '?', and (often) '!', respectively. Clause type is formally defined by morphosyntax, lexis, and prosody.

(1) He just wouldn't stop whining. Bill was shot by Max. Bill, Max shot. Bill died. Max gave the Salvos a donation. *It's snowing* is a declarative sentence. Mortgage rates down at last. Dunno who did it.
(2) Will you stop whining? Care to come along? Which came first? The chicken or the chicken nuggets? Why bother? After all, who wants to crash a convivial high by spending an hour at the sink? I shouldn't have worn those heels today, should I? He's not bad, huh? Please may I be excused? You were where on the night of eighteenth May?
(3) Stop your bloody whining! Move it, Grandma. Be warned! Get yourself checked by someone qualified. You give me that ball, you! Nobody move! Let the Games begin. Let me help. Let's eat. Have a good day!

The western classical tradition in linguistics identifies three **moods**: indicative, subjunctive, imperative – which partially correspond to clause types. Protagoras (490–420 BCE, Diogenes Laertius, Book IX) splits the indicative into interrogative [erōtēsis] and declarative [apokrisis]. Palmer (2001) recognizes only two moods: indicative and subjunctive, which he compares with the realis-irrealis division proposed for some Native American languages (Chafe, 1995; Mithun, 1995) and Papuan languages (Roberts, 1990); and also with the assertive/non-assertive division proposed by Quirk, Greenbaum *et al.* (1985), Wierzbicka (1988), and Lunn (1995). Cross linguistically, there is a cline between indicative/realis/assertive at one pole and subjunctive/hypothetical/irrealis/uncertain at the other (Givón, 1994; Wehmeier, 2004).

The semantics of a clause type is its **primary illocution** (PI). All languages have a **declarative** as the most frequent and least marked clause type; here its PI is symbolized **T**, because its token potentially bears a truth value when used by a speaker in an utterance in a certain context (*see* **Type versus Token**). The declarative is typically realis (though it may include a hypothetical). At the opposite extreme is the PI **H**, characteristic of hypotheticals, counterfactuals, intensionals, traditional subjunctives, and other irrealities. Like the subjunctive (Givón, 1994: 277; Jespersen, 1958: 318), hypotheticals often have no unique morphology. Between the extremes of **T** and **H** are strung interrogatives, imperatives, negatives, futures, and habituals which may align with **T** or with **H**. For instance, 'Jim is not here' describes an event that can be seen as a factual statement having a truth value; and therefore aligned with **T**; alternatively, it is a counterfact aligned with **H**. A question 'Who

Sadock and Zwicky (1985) surveyed 35 languages representing a wide range of language families and linguistic areas. They found that every language distinguishes at least three **clause types**: declaratives (1), interrogatives (2), and imperatives (3). It is surely no accident that these are the clause types orthographically marked by '.', '?', and (often) '!', respectively. Clause type is formally defined by morphosyntax, lexis, and prosody.

(1) He just wouldn't stop whining. Bill was shot by Max. Bill, Max shot. Bill died. Max gave the Salvos a donation. *It's snowing* is a declarative sentence. Mortgage rates down at last. Dunno who did it.
(2) Will you stop whining? Care to come along? Which came first? The chicken or the chicken nuggets? Why bother? After all, who wants to crash a convivial high by spending an hour at the sink? I shouldn't have worn those heels today, should I? He's not bad, huh? Please may I be excused? You were where on the night of eighteenth May?
(3) Stop your bloody whining! Move it, Grandma. Be warned! Get yourself checked by someone qualified. You give me that ball, you! Nobody move! Let the Games begin. Let me help. Let's eat. Have a good day!

The western classical tradition in linguistics identifies three **moods**: indicative, subjunctive, imperative – which partially correspond to clause types. Protagoras (490–420 BCE, Diogenes Laertius, Book IX) splits the indicative into interrogative [erōtēsis] and declarative [apokrisis]. Palmer (2001) recognizes only two moods: indicative and subjunctive, which he compares with the realis-irrealis division proposed for some Native American languages (Chafe, 1995; Mithun, 1995) and Papuan languages (Roberts, 1990); and also with the assertive/non-assertive division proposed by Quirk, Greenbaum *et al.* (1985), Wierzbicka (1988), and Lunn (1995). Cross linguistically, there is a cline between indicative/realis/assertive at one pole and subjunctive/hypothetical/irrealis/uncertain at the other (Givón, 1994; Wehmeier, 2004).

The semantics of a clause type is its **primary illocution** (PI). All languages have a **declarative** as the most frequent and least marked clause type; here its PI is symbolized **T**, because its token potentially bears a truth value when used by a speaker in an utterance in a certain context (*see* **Type versus Token**). The declarative is typically realis (though it may include a hypothetical). At the opposite extreme is the PI **H**, characteristic of hypotheticals, counterfactuals, intensionals, traditional subjunctives, and other irrealities. Like the subjunctive (Givón, 1994: 277; Jespersen, 1958: 318), hypotheticals often have no unique morphology. Between the extremes of **T** and **H** are strung interrogatives, imperatives, negatives, futures, and habituals which may align with **T** or with **H**. For instance, 'Jim is not here' describes an event that can be seen as a factual statement having a truth value; and therefore aligned with **T**; alternatively, it is a counterfact aligned with **H**. A question 'Who

is that?' has no truth value (*It is true that who is that), thus it can align with **H**; but in the Western classical tradition it is indicative and aligned with **T**. In the space here, it is unrealistic to force all languages into a universal mold any more specific than that already described; so the focus is on English.

Coincidence between clause type and illocutionary force may have been recognized by Protagoras, certainly by Apollonius Dyscolus (100 CE); cf. Householder (1981); Sanctius (1585); Lancelot (1644); Lane (1700); Whitney (1888); Sadock (1974); Van Valin and LaPolla (1997); and Huddleston and Pullum (2002).

How does illocutionary force enter the picture?

- Linguistics is concerned (*inter alia*) with utterances in which Speaker uses a language expression and thereby performs a locutionary act; to do so, Speaker uses an identifiable sentence or clause fragment from a language L (sentence type, intonation type, etc.). The resulting token is a locution.
- Producing the locution demands that Speaker has knowledge of the morphosyntax, lexicon, semantics, and phonology of the language used. Recognizing the locution demands that Hearer has comparable knowledge.
- A locution will normally bear more than one illocutionary force (e.g., 'I'll see you at 10' is a statement, prediction, (potentially) commissive); yet, it will usually have only one message to convey (depending on context, perhaps a promise or a threat). The illocutionary force that carries this message is called the illocutionary point of the utterance.
- The form of the locution in the utterance must be the starting point for Hearer's interpretation of the utterance meaning. Thus, Hearer must seek to recognize (a) the locution, including the sense of each clause; (b) what Speaker intends the locution to refer to; and (c) the illocutionary forces within the utterance that give rise to its illocutionary point. Hearer hears the locution, recognizes its sense, looks to the context to figure out the apparent reference, and then seeks to infer Speaker's illocutionary intention.
- Speaker's illocutionary intention is to have Hearer recognize the illocutionary point of Speaker's utterance in order to achieve a particular perlocutionary effect – the behavioral and/or cognitive and/or emotional response to the illocutionary forces in the utterance. Speaker's perlocutionary act is an act of achieving a particular perlocutionary effect on Hearer as a result of Hearer recognizing (what s/he takes to be) the locution and illocutionary forces in Speaker's utterance.
- Recognizing the clause type is the first step toward discovering the illocutionary point via the PI. It is important to reaffirm that the PI is the semantic property of the clause type (details are given shortly). The PI of 'I'll see you at 10' is a statement (with its potential truth value); the statement makes a prediction about the Speaker's future behavior which, entering the pragmatic domain, typically constitutes a commissive; in turn, this commissive may be a promise or a threat depending on several contextual factors. The PI is one semantic basis for the pragmatic inferencing that leads to the illocutionary point.

What criteria identify clause type? Word order distinguishes declarative 'He is tall' from interrogative 'Is he tall?' Morphosyntactic marking distinguishes the hypothetical backshifted modal in the temporally non-past '**Could** you mail this letter for me?' from the indicative '**Can** you mail this letter for me?', and these two interrogatives from the declarative 'I can certainly mail it for you.' Intonation distinguishes declarative from interrogative versions of 'John's gone to New York(./?)' Similarly, in other languages: In Navajo, the imperative has the same morphosyntax as the declarative, but is prosodically distinct; in Korean, declarative, interrogative, imperative, and propositive ('let's' constructions) are formally identical in intimate and polite speech levels, but are distinguished by prosody. In addition to prosodic marking, the interrogative 'John's gone where?' is lexically marked by the wh- word at the questioned location. Lexical marking is significant in identifying interrogatives in subordinate clauses: 'She asked **how / whether / if** John had traveled to New York.'

Many (uttered) subsentences (clause fragments whose missing constituents are recoverable from context) clearly function like well-established clause

Table 1 The declarative PI

<form>	**T**[Φ], see (1). The typical prosody involves downdrift.
<description>	Speaker says that Φ. (Declaratives potentially have truth values.)
<precondition>	Speaker has reason to believe that Φ.
<illocutionary intention>	Speaker reflexively intends the utterance of the clause to be recognized as a reason for Hearer to believe that Speaker has reason to believe that Φ. (Notice Speaker's purported commitment to the truth of what is being said.)

types. It is prosody (or its typographic counterpart) that distinguishes interrogative 'John?' ['Is that you?'] and imperative 'JOHN!' ['Come in at once!'] from each other and from declaratives. An utterance of the name 'John' in answer to 'Who's that?' must be judged declarative on prosodic and contextual grounds. The clipped clause 'If only!' is judged hypothetical on lexical and perhaps also contextual grounds. Such subsentences seem intuitively to function like distinct clause types and to have distinct PIs.

The primary illocution of a **declarative**, the default clause type, is defined in Table 1 below. In the definition the precondition ('preparatory condition,' Austin, 1975) establishes proper grounds for uttering a declarative clause. The illocutionary intention of a declarative arises directly from Speaker's use of it, given the precondition. As its primary illocution, the declarative performs an act of saying that Φ. The fact that declaratives (potentially) have truth values is the principal way to positively identify them. A declarative illocution is the primary illocution and not the illocutionary point of an utterance. There are few illocutionary points that cannot be achieved using a declarative: e.g., declaratives 'I'm asking what your name is,' 'I'm telling you to stop making that noise' issue directives. Performatives such as 'I promise to be good', 'You are prohibited from smoking' also have the primary illocution of a declarative (*see* **Performative Clauses** for discussion).

The PI of **interrogatives** is exemplified in Table 2. The purported option for the Hearer to refuse or plead inability to comply distinguishes interrogatives from imperatives – which purportedly offer no such option. These different options are what make interrogatives (askings) 'more polite' than imperatives (tellings) – but the pragmatics of the comparative uses of interrogatives and imperatives are too complex to be adequately discussed here.

Imperatives have the PI as shown in Table 3. Many imperative clauses are entreaties; they include supplications to someone powerful or wronged ('Forgive me'), propositives ('Let's eat'), and instructions which are of primary benefit to Hearer ('Have a nice day!'). Cross linguistically, first and third person 'imperatives,' often called 'jussives,' are frequently subjunctive (Palmer, 2001).

English has two independent **hypothetical** constructions that contrast with the three major clause types (see Table 4). Otherwise, in English, hypotheticals occur within the scope of declaratives, interrogatives, and imperatives, whose prosody they adopt along with their values. Hypotheticals may occur within the scope of a declarative, **T**, such that they (potentially) have truth values within some hypothetical world; for example, the complement of a verb of wishing. In **T**[I wish **H**[I were rich]], the 'were' is backshifted, i.e., looks like a past tense, but is in fact the nonpast derived from Old English subjunctive 'wǣre' (past tense would be 'I wish(ed) I **had been** rich'). In conditional **I**[**H**[If Harry should call], tell him 'No'], the protasis invokes a hypothetical world; the apodosis is imperative and supplies the PI. Within interrogatives, **Q**[**H**[Φ]], ('Could you mail this for me?'), the hypothetical is marked by one of four

Table 2 The interrogative PI

<form>	**Q**[Φ]. Lexical markers such as post clausal English 'eh?', clause final Japanese 'ka', English 'wh'- words, 'if' and 'whether' in subordinate clauses, and/or morphosyntactic markers such as subject-auxiliary inversion in main clauses. Because rising intonation typically marks orientation toward Hearer, interrogatives typically display updrift.
<description>	Speaker asks Hearer something—makes a request (cf. Allan, 1986; questions are requests for information to be delivered verbally). There is a purported option for the Hearer to refuse (or plead inability) to comply.
<precondition>	Speaker purportedly believes that Hearer can or might be able to respond appropriately to what is asked in the clause.
<illocutionary intention>	Speaker reflexively intends the utterance of the clause to be taken as asking Hearer something.

Table 3 The imperative PI

<form>	**I**[**F**[Φ]]. Prosodic marking: falling intonation. Imperatives occur only in independent clauses (including coordinate and appositive clauses). The verb is in the base form and non-past tense, but semantically future (**F**).
<description>	Speaker directs or entreats Hearer to do A. The direction or entreaty is present time, the act A is future – though often expected to start immediately. There is purportedly no option for the Hearer to refuse (or plead inability) to comply.
<precondition>	Speaker purportedly believes that Hearer can do A.
<illocutionary intention>	Speaker reflexively intends Hearer to take the utterance of the clause as a reason to do A.

Table 4 The hypothetical PI

<form>	**H**[Φ] where Φ is either 'Would that S' (e.g., 'Would that I were rich') or 'May S' ('May he rot in hell!') in which 'Would' and 'May' are main verbs using the root senses of these modals, and in which neither 'Would' nor 'May' can be negated.
<description>	Speaker vehemently wishes (hence the root senses) that the proposition in S may (or may have) come about in some hypothetical world accessible from the real world in which the utterance takes place.
<precondition>	Speaker has some reason to wish that S may (or may have) come about.
<illocutionary intention>	Speaker reflexively intends the clause to be taken as a reason for Hearer to believe that Speaker vehemently wishes that S may (or may have) come about in some hypothetical world.

backshifted modals: 'could,' 'might,' 'should,' 'would.' What is here called *hypothetical* is often referred to as *subjunctive mood*; but the fact that it occurs within the scope of other moods makes this classification problematic—at least for those who wish to retain traditional definitions of mood.

Expressives are not traditionally recognized as a clause type because none are full syntactic clauses, e.g., 'Goodness gracious!' 'Wow!' 'Jesus!' 'Thanks.' 'Congratulations.' 'Hi.' 'Bye.' 'Good luck!' They can be distinguished on semantic and lexical-cum-morphosyntactic grounds; they are short and usually verbless. Like clauses, they can stand alone in expressing a complete thought. They are **idioms**, often with idiomatic counterparts in other languages. They do not admit passivization or negation. Expressives do not have truth values, so they are not declaratives; they do not make requests, so they are not interrogatives; they do not direct or entreat, so they are not imperatives. Some are subjunctive. Their principal function is to display a sometimes perfunctory, sometimes strongly felt emotive reaction or social interaction toward something that has occurred. One subset of them will serve to illustrate all. 'Thanks' is presumably foreclipped from 'I offer you my thanks.' However, one can't willy-nilly strip out the possessed noun from a string 'I offer (you) my NOUN' to create a synonymous utterance. The monosyllable 'Book' could, in a well-defined context such as proffering the book, be interpreted as 'I offer you my book'; but this not the kind of condition applicable to 'Thanks.' Furthermore one cannot foreclip 'I offer you my help' to create the monosyllable 'Help', which is imperative. Apparently, utterances with an expressive illocutionary point facilitate the creation of brief idiomatic counterparts for ritualized behavior and to satisfy the constraints on verbal ejaculation. 'Thank you' is normally subjectless and idiomatic by contrast with the declarative 'I/We thank you.' It is not part of a normal paradigm: It is not imperative like 'Thank him.' It cannot be tensed: 'Thanked you' is perhaps possible as an aphetic diary entry, but not as a normal report of past behavior. Both 'Thanks' and 'Thank you' are reported like any declarative ('I thanked him') – which is normal for expressives. 'No thanks' and 'No thank you' are idiomatizations of two separate subsentences ('No, thanks' / 'thank you') from which the disjuncture has disappeared. 'Thanks' and 'Thank you' mean 'I thank you'; their negation is 'I don't thank you.' This is not the meaning of 'No thanks' / 'thank you' which are explicit rejections of an offer; just as 'Yes, thanks' is an acceptance.

Exclamatives occur within the other clause types and do not count as a distinct clause type in their own right (despite the way they are discussed here). Exclamatives are all prosodically marked by exaggerated acoustic intensity (wide-ranging peaks and troughs) that is indicated orthographically by an exclamation mark, '!', and there is lexical marking of some declarative exclamatives by clause initial 'how' and 'what' immediately followed by the preposed clause constituent in the focus of exclamation ('What a bloody whiner he was!' 'How she hated it!'). Speaker expresses within Φ a forcible, emphatic, or vehement point of approbation, delight, pleasure, pain, surprise, anger, irritation, etc.; the reflexive-intention is to focus Hearer's attention on a part of what is being said in Φ as being of particular importance in the context of the communication in progress; but this is just a modification on the PI of the governing clause type. The same might be said of hypotheticals when they do not contrast with the other clause types, which is one reason to deny that there is a subjunctive mood in English.

Primary illocution (PI) is the semantics of clause type or corresponding subsentence. Declarative, interrogative, imperative, subjunctive, expressive, exclamative clause types or subsentences are identified through morphosyntactic, lexical, and prosodic form, their use in main and subordinate clauses, and behavior under negation. The PI is identified with Speaker's illocutionary intention in using the clause type/subsentence. This PI is the starting point for Hearer inferring the illocutionary point of (Speaker's message in) the utterance containing the clause, in the manner first described in Searle (1975) (see also Bach and Harnish, 1979; Allan, 1986, 2001). It is probable that all languages have most of the clause types/subsentences described here. Further research is

needed to systematically accommodate conditionals, imprecatives, jussives, laudatives, obligatives, optatives, prohibitives, propositives, and purposives within the network of relations manifest by clause types and illocutionary forces. Exactly how all these are to be related to the traditional category of mood remains to be seen.

Morgenstierne, Georg (1892–1978)

D Haug, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

The Norwegian Iranist Georg Morgenstierne studied Indo-European linguistics and Indic and Classical Philology at the University of Kristiania (now Oslo) and went on to further studies of Indology and comparative linguistics in Bonn and Berlin. In 1918, he received his doctorate in Berlin for a philological study on Indian drama, but for the rest of his life he was to pursue linguistic studies, especially on the Indo-Iranian languages. He became a professor of comparative linguistics and Sanskrit in Göteborg in 1930 and then, from 1937, professor of Indian language and literature in Oslo.

Morgenstierne's linguistic achievements concern the study of Iranian languages, especially the Indo-Iranian frontier languages. He made several trips to Asia, the first to Afghanistan in 1923–1924, after the foundation in Oslo of the Institute for Comparative Research in Human Culture had made funding possible. On these journeys he not only collected data that formed the basis of his published linguistic work, but also made many audio and video recordings now kept at the Norwegian National Library.

His first journey to Afghanistan resulted in *A report on a linguistic mission to Afghanistan* (Oslo, 1926) that gave short descriptions of the languages of Afghanistan and for the first time presented a thesis that Morgenstierne would defend in several publications during his life, namely that the Kafir languages of Nuristan represented a separate subgroup of Indo-Aryan. He also published *An etymological vocabulary of Pashto* (1927). This was the beginning of a life-long pursuit of Pashto studies. When he died he was still working on a second edition of this work, which was later completed by J. Elfenbein *et al.* (Wiesbaden, 2003).

After his first journey he also published the first volume of his monumental *Indo-Iranian frontier languages* (1929), to which he would later add three more volumes describing the languages of the border areas between Indian and Iranian (the whole work was republished in 1973). Methodologically, this work, like everything else he wrote, is characterized by his training in the Neogrammarian paradigm. Morgenstierne was never concerned with linguistic theory as such, but rather with the collection of linguistic data and their interpretation in a historical and etymological perspective. Although many of his descriptions of Iranian languages have been superseded by later studies, his work remains fundamental, especially for the historical dialectology of East Iranian.

Morocco: Language Situation

F Sadiqi, Sidi Mohamed Ben Abdellah University, Fes, Morocco

© 2006 Elsevier Ltd. All rights reserved.

Four major languages are used in Morocco: Berber, Standard Arabic, Moroccan Arabic, and French, and two minor ones: Spanish and English. Each one of these languages has a special status in the overall Moroccan linguistic market.

Berber is the oldest language in Morocco and indeed in North Africa (cf. Ayache, 1964; Laroui, 1977; Chafik, 1982). It is an Afro-Asiatic language (cf. Cohen, 1947; Basset, 1952; Galand, 1960), genetically related to Old Egyptian (Coptic), Cushitic, Chadic, and Semitic. Three major varieties of Berber are found in Morocco: Tashelhit in the south, Tamazight in the center, and Tarifit in the north. According to the 1994 official statistics, Morocco has 28 million inhabitants, of which 30% speak one of the Berber varieties. However, some linguists state that almost half of the Moroccan population speaks Berber (Boukous, 1995; Ennaji, 1997; Sadiqi, 1997b). In September 2004, Berber started to be taught in 300 Moroccan primary schools after its codification through its original alphabet, Tifinagh. This initiative was preceded by the creation of the Royal Institute of the Amazigh Culture in October 2001.

As for Standard Arabic, it is a modern version of Classical Arabic, the language of the Qur'an and pre-Islamic poetry. Standard Arabic was introduced in Morocco at the end of the 7th and the beginning of the 8th centuries from the East and Islamic Iberia. At the present time, Standard Arabic is the official language of Morocco. It is used in the key formal and powerful domains, namely religion, government, education, and the media. It has great prestige as the 'language of God' and as the unifying language of the Arab world (*al-umma al-çarabiyyah*) and the

Morocco: Language Situation

F Sadiqi, Sidi Mohamed Ben Abdellah University, Fes, Morocco

© 2006 Elsevier Ltd. All rights reserved.

Four major languages are used in Morocco: Berber, Standard Arabic, Moroccan Arabic, and French, and two minor ones: Spanish and English. Each one of these languages has a special status in the overall Moroccan linguistic market.

Berber is the oldest language in Morocco and indeed in North Africa (cf. Ayache, 1964; Laroui, 1977; Chafik, 1982). It is an Afro-Asiatic language (cf. Cohen, 1947; Basset, 1952; Galand, 1960), genetically related to Old Egyptian (Coptic), Cushitic, Chadic, and Semitic. Three major varieties of Berber are found in Morocco: Tashelhit in the south, Tamazight in the center, and Tarifit in the north. According to the 1994 official statistics, Morocco has 28 million inhabitants, of which 30% speak one of the Berber varieties. However, some linguists state that almost half of the Moroccan population speaks Berber (Boukous, 1995; Ennaji, 1997; Sadiqi, 1997b). In September 2004, Berber started to be taught in 300 Moroccan primary schools after its codification through its original alphabet, Tifinagh. This initiative was preceded by the creation of the Royal Institute of the Amazigh Culture in October 2001.

As for Standard Arabic, it is a modern version of Classical Arabic, the language of the Qur'an and pre-Islamic poetry. Standard Arabic was introduced in Morocco at the end of the 7th and the beginning of the 8th centuries from the East and Islamic Iberia. At the present time, Standard Arabic is the official language of Morocco. It is used in the key formal and powerful domains, namely religion, government, education, and the media. It has great prestige as the 'language of God' and as the unifying language of the Arab world (*al-umma al-çarabiyyah*) and the

Muslim world (*al-umma al-islaamiyyah*). It is also a symbol of identity, especially outside Morocco and the Arab world. After independence, and especially since the 1960s, the policy of language planning in Morocco was characterized by the Arabization of the different sociocultural sectors, especially the mass media, education, and governmental administrations. This Arabization proceeded with varying and debatable success (cf. Grandguillaume, 1983).

Although Moroccan Arabic (or *darija*, derived from the Standard Arabic verb *daraja*, which means 'spread among' or 'proceed gradually') shares many linguistic aspects with Standard Arabic, it is structurally different as it has simpler morphosyntax, lexicon, and phonology (cf. Ennaji and Sadiqi, in press). Like Berber, Moroccan Arabic is not a homogeneous language in form, as various Moroccan Arabic dialects are spoken in various geographical areas of Morocco. However, unlike Berber, Moroccan Arabic is the lingua franca in Morocco, its wider use has reduced the interdialectal differences and allowed intercomprehensibility between the Moroccan Arabic dialects. Moroccan Arabic is used in family circles, among friends, in commerce, on television, in the theater, and in the cinema.

French is a second language in Morocco; it is also the country's window on the West. Five factors have contributed to the maintenance of French: (a) Morocco's economic dependence on France, (b) social factors (the requirement of French in the job market, especially in the private sector), (c) historical factors, (d) immigration, and (e) tourism. It is in the domain of education that French has the most prestige in Morocco. This strong position of French in Morocco has given rise to bilingualism (Arabic/Berber and French) and to code-switching (see Sadiqi, 2003).

Spanish was introduced in Morocco in the 17th century. In spite of 300 years of presence in the country, this language has had much less impact on Moroccan culture than French because it has not been used as a means of communication, except in the North by Rifian Berbers and in the Rio de Oro region, where it has had some effect (the Spanish did not formally withdraw from the latter region until 1975). Nowadays, the younger generations in the north of Morocco use Spanish less and less. Further, unlike French, Spanish has never been used in the Moroccan administration and its use in the educational system has remained limited. As for English, it was introduced in Morocco during World War II when Americans established military bases on Moroccan territory to link them to battlegrounds in Europe. The presence of English has been greatly enhanced by tourism, the movies, music, and now globalization. The international status of English as the language of science and technology, business, cyberspace, and research, even by French-educated Moroccans, has also contributed to the spread of English (cf. Sadiqi, 1991). Nowadays, English has supplanted Spanish in the economy and education, and is competing with French in education. It is the fastest growing language in Morocco. The new American style University of Al-Akhawayne has greatly boosted the status of English in Morocco.

Morpheme

M Aronoff and M Volpe, Stony Brook University, Stony Brook, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

A remarkable number of the terms we use today were coined by the Polish linguist Jan Baudouin de Courtenay in the 1880s, among the most prominent being 'morpheme.' Baudouin defined the morpheme as "that part of a word which is endowed with psychological autonomy and is for the very same reasons not further divisible." Curiously, despite the fairly speedy widespread adoption of Baudouin's term 'phoneme' by Saussure and others, the term "morpheme" did not become popular until it was adopted by Bloomfield in his *Language* in 1933. Bloomfield's definition of this term is characteristically precise and opaque: "a linguistic form which bears no partial phonetic-semantic resemblance to any other form, is a *simple* form or *morpheme*." (Bloomfield, 1933: 161). He goes on to write that "... it appears that every complex form is entirely made up, so far as its phonetically definable constituents are concerned, of morphemes." The term "simple form" appears to echo Saussure's distinction between simple and complex signs, but while Bloomfield's morpheme is equivalent to Saussure's sign, it is Bloomfield's (or more properly Baudouin's) term that has become more widely accepted in technical linguistics (quite likely because of its exotic sounding name and similarity to other exotic technical terms).

The Baudouin/Bloomfield morpheme, like Saussure's sign, must be a concrete unit: a morpheme for Bloomfield and for Baudouin must have continuous segmental phonetic content. This means that not all of the elements that many modern linguists think of as morphemes were morphemes for Bloomfield, because, while these modern linguists think of morphemes first in terms of meaning, for Bloomfield there could also be grammatically meaningful elements that were not morphemes, because they did not have segmental content. Having a grammatically isolated meaning was a necessary but not sufficient condition for calling something a morpheme; having form and meaning together was both necessary and sufficient for morphemehood.

This means that when we read Bloomfield from a modern perspective, we sometimes find his analyses puzzling. Thus, on the page where he first defines the term 'morpheme,' Bloomfield explicitly analyzes the English verb *ran* as a single morpheme, even though it is grammatically complex, being the past tense of the verb *run*. For Bloomfield, *ran* could not possibly consist of two morphemes, say [*r* ... *n*] and [*a*], since [*r* ... *n*] would be discontinuous and hence not phonetically concrete (leaving aside the problem of relating *run* and *ran*). Bloomfield solves both the problem of the complexity of *ran* and its relation to *run* by analyzing both the past tense form *ran* and the infinitive form *run* as alternants, calling the infinitive basic and the past tense "phonetically modified". Phonetic modification, not being segmental, could not be a morpheme for Bloomfield, although it could be grammatically meaningful.

Later on (Bloomfield, 1933: 216), in discussing plurals like *mice* and *geese*, Bloomfield writes that "In these plurals, a grammatical feature, phonetic modification, expresses a meaning (namely the sememe '*more than one* object') which is normally expressed by a linguistic form (namely the morpheme [-ez, -z, -s]). We may say that 'substitution of [ij]' in *geese* ... [*and*] 'substitution of [aj]' in *mice* ... are alternants of the normal plural-suffix *substitution-alternants* or *substitution-forms*." He then goes on to extend this analysis to English past tense verbs like *ran*. But nonetheless Bloomfield insists that words like *ran* consist of "only one morpheme, accompanied by a ... substitution feature" (Bloomfield, 1933: 218), though he recognizes the peculiarity of words like *ran* and *mice* by calling them secondary morpheme-words. To repeat, a substitution feature cannot be a morpheme, because for Bloomfield morphemes must be segmental. It is important to note, though, that substitution can nonetheless be meaningful. In other words, unlike his modern descendants, Bloomfield allowed two kinds of meaningful entities, only one of which he called morphemes.

But if operations like substitution are not morphemes for Bloomfield, because they are not segmental, even though they may be meaningful, then what are they? For him they are features of arrangement or grammar and he makes a fundamental opposition between grammar and the stock of morphemes or lexicon. Bloomfield distinguished four structural types of potentially meaningful grammatical features (or 'taxemes'): order, modulation, phonetic modification (including substitution), and selection. But because phonetic modification can be meaningful for Bloomfield and yet still not morphemic, his famous pronouncements that "Since every complex form is made up entirely of morphemes, a complete list of morphemes would account for all the phonetic forms of a language" (Bloomfield, 1933: 162) and that "every complex form is made up entirely of morphemes" (Bloomfield, 1933: 161) must be read especially carefully: Bloomfield's morphemes exhaust the

sound of the complex form (at least its segmental aspect), but they do not exhaust its **meaning**.

Beginning shortly after Bloomfield, linguists began to believe that language should consist entirely of morphemes and their arrangement (a belief to which Saussure may have contributed) and that even non-segmental processes like substitution or subtraction, which Bloomfield had explicitly refrained from calling morphemes, should by some means be reduced to Bloomfieldian morphemes. Hockett and others in the 1940s and 1950s believed that by "following a pattern that had proved eminently successful in dealing with [*languages*'] sound aspect . . . morphemes are, on the grammatical level, what phonemes are on the phonological level" (Hockett, 1987: 65). This belief could only be enhanced by the positivist culture that Bloomfield inculcated in his followers. After all, if we are only permitted to posit the existence of entities that have some sort of physical existence, then meaningful elements that are not possessed of segmental substance become a distinct embarrassment.

While Bloomfield's definition of morpheme was clear, the criterion for identity among individual morphemes was only implied. For the Structuralists who followed Bloomfield, abstract units of meaning, Bloomfield's sememes, consisted of allomorphs, alternants that subsumed grammatically equivalent units at the level of the morpheme (Harris, 1942). Under this approach, the phonological variants are called morphs, the abstract unit, e.g., [PLURAL] and [PAST], morphemes.

Such reductionism was reinforced by the generative phonology movement, in which, under the influence of Roman Jakobson, much effort was expended to reduce alternants such as *run* and *ran* or the allomorphs of the English *-s* plural to single invariant underlying forms, from which the alternants could then be produced by rule. The apparent success of the generative program in phonology reinforced the hope that, at some level of analysis, language could be reduced to phonetically contentful Bloomfieldian morphemes. By contrast, much morphological theory over the last two decades (Matthews, 1991; Anderson, 1992; Halle and Marantz, 1993; Aronoff, 1994; Beard, 1995) in reaction to both these trends, has instead tried to deal head on with the problems that first led Bloomfield to define the morpheme in the way that he did.

One way of dealing with Bloomfield's distinction between meaningful modification and meaningful form is to concentrate instead on what the two have in common, meaning, uniting both under the term "morpheme" and thereby changing the focus of the term and of morphology itself. Distributed Morphology (Halle and Marantz, 1993) defines morphemes quite explicitly in terms of syntax alone as the terminal elements of syntactic trees, regardless of whether they are filled by segmental phonological exponents or not. These terminal elements are complexes of grammatical features. (Halle and Marantz, 1993: 114). Later work in Distributed Morphology (Harley and Noyer, 2000) recognizes a distinction between L-morphemes (lexical morphemes) and F-morphemes (functional morphemes). L-morphemes are the terminal nodes of categorically unspecified roots, which are, by stipulation, featureless; F-morphemes are feature bundles whose exponents including NULL are inserted in accord with the subset principle. Thus, for an element to be called a morpheme in this theory, it is not necessary that it be simultaneously realized phonologically, as Bloomfield insisted. The theory deals with the problem that led to Bloomfield's definition of the morpheme by redefining the morpheme in terms of meaning alone.

Lexeme-Morpheme Base Morphology (Beard, 1995) employs the French functionalist usage (Martinet, 1960) whereby the term 'morpheme' is reserved for only the closed-class functional forms, e.g., adpositions, pronouns and affixes (Martinet's term for something akin to the post-Bloomfieldian morpheme is 'monème'). Beard uses the term 'lexeme' (Matthews, 1992) for the open-class categories verb, noun and adjective.

Anderson's A-morphous Morphology (1992) asks the provocative question "Is morphology really about morphemes?" (Anderson, 1992: 48), to which he replies with a resounding "No!". Anderson discusses various classical problems with the morpheme including the existence of structure without meaning, e.g., Aronoff's *-ceive* morphemes (1976), empty morphs such as the Latin thematic vowels, and portmanteau morphs, e.g., the French *du* 'of the' (= *de* + *le*). Anderson's problem with the morpheme is not with these problematic cases, *per se*, but with the usefulness of the classical Bloomfieldian morpheme, to which he attributes no synchronic relevance. For Anderson, words are not related by virtue of their containing identical morphemes, but rather by word formation rules (WFR) (Aronoff, 1976), which derive the more complex word from an existing word (also perhaps derived by a previous WFR).

Aronoff (1994) introduces a new term, 'morphome,' to identify morphological units whose identity is established on purely formal grounds, independent of meaning, in the spirit of Harris (1951). Consider the English verb *stand*, whose past tense form is *stood*. The verbs *withstand* and *understand* similarly have the past tense forms *withstood* and *understood*, yet we would be hard pressed to claim that these two verbs are semantically related

to the sense of the free verb *stand*. What they share is a stem whose default form is *stand* and whose form is *stood* when the verb that contains it is PAST. Aronoff calls such stems and other units that are identified purely in terms of formal alternations morphomes and uses the existence of morphomes to argue for an autonomous morphological component in language.

Bloomfield's original definition of the term 'morpheme' fell into disuse quite quickly after its first promulgation. It was replaced by either an ideology that wished away the entire category of meaningful nonmorphemic processes that Bloomfield so carefully distinguished from morphemes or, failing that, by a more recent definition in which the distinction between meaningful form and meaningful process is declared moot. Still, the central argument in morphology over the last decade has been about whether the distinction that Bloomfield made by defining the morpheme as precisely as he did is valid. So, if we are asking whether theorists are still haunted by the sort of phenomenon that led Bloomfield to his peculiar definition of the morpheme, then the answer must be that Bloomfield's morpheme is still a useful notion. And if we are to take away a lesson from all this it is the enduring value of precise distinctions, especially when made by a master who knew where to draw them.

Morphological Change, Paradigm Leveling and Analogy

C Reiss, Concordia University, Montreal, Canada

© 2006 Elsevier Ltd. All rights reserved.

In this article, I assume that all so-called language change, including analogy, is best understood as a relationship between grammars instantiated in different minds at earlier and later points in time (Hale, 2005). Thus, analogy is not a property of any particular mental grammar, but we can nonetheless gain insight into such diachronic processes by considering them from the perspective of a theory of language acquisition in the generative tradition.

The change from Early Modern English *reach/raught* to *reach/reached* represents one kind of analogy, referred to as paradigm leveling. This change decreases allomorphy for a given verb, but is by no means general, since *teach/taught* survives. Four part proportional analogy can be illustrated by the pronunciation *my*[θ]/*my*[ðz] (as against historically prior *my*[θ]/*my*[θs]) by some speakers of English. This type of analogy may increase allomorphy, and in this particular case it resulted in parallelism with paradigms such as *ba*[θ]/*ba*[ðz]. The name derives from the fact that the analyst can set up a proportion as follows, and solve for X:

Four-part proportional analogy: ba[θ] : my[θ] :: ba[ðz] : X, X = my[ðz]

Many examples of both kinds of analogy can be found in a standard historical text such as Hock (1991). The two types are typically treated as distinct, but in fact are probably unifiable, since analysis of paradigm leveling implicitly involves comparison with other paradigms: *reached* was formed, in some sense, because other verbs gave evidence for a separable past tense morpheme that could be added to the present stem. We, however, maintain the traditional distinction in what follows.

Both these English examples present some difficulties, because the analysis of the synchronic patterns (suppletion in the case of *teach/taught* and apparently irregular phonology in the case of the voicing alternations) is controversial. However, we retain them because of the familiarity of the data.

No 'explanation' of language change will be able to state why a given change occurred at a particular time and place; at most we can suggest why such a reanalysis was possible or perhaps even probable under certain conditions. Furthermore, given our conception of language change, it is apparent that no grammar-internal principle, universal or particular, can account for any example of language change, whatsoever: the prechange and postchange stages are both possible languages, so the cause of the change cannot possibly be the fact that the prechange stage is incompatible with Universal Grammar. Although widely ignored in generativist writings on language change, the essence of this fundamental principle was articulated already by Bloomfield (1933: 386).

So, if analogies of the type shown cannot be identified as computations of synchronic grammars, where do the patterns come from – is the analyst's analogy just a fiction? I propose that the analogies reflect the process of lexicon building during language acquisition. Retaining the notion that language change refers to a relationship between various grammars, we can ascribe the analogies to a difference in the lexicons at two stages of a 'language,' that is, two grammars, the output of one serving as the PLD for the construction of the other.

The example referred to as paradigm leveling is particularly easy to account for under these assumptions. The change from stage 1 *reach/raught* to stage 2 *reach/reached* merely reflects a failure by the stage 2 speaker to internalize the form *raught*. In the absence of a stored past tense form for this verb, the speaker applies the productive, default past tense formation rules, learned on the basis of numerous other data points, and generates the regular form *reached*. If *raught* had been acquired, it would block the formation of *reached*.

Accounting for proportional analogy is more difficult: it cannot be a failure to internalize *my*[θs] that automatically leads a speaker to produce *my*[ðz]. Since no grammatical principle can explain this, the relevant factor must be accidental priming effects. Assume that a stage 1 speaker has *my*[θ]/*my*[θs] and *ba*[θ]/*ba*[ðz]. Suppose that this output has allowed a learner to acquire *ba*[θ]/*ba*[ðz], and suppose that such forms have just been uttered in the presence of the learner. Upon presentation of the form *my*[θ], which is ambiguous as to whether it is a plain, regular form, or a form that has a voicing alternation, the recency of the *ba*[θ]/*ba*[ðz] token (even just one element of the pair) will prime the [θ]/[ð] alternation, and lead the learner to override the default parse and set up a representation for *my*[θ] that mimics that which she already has for *ba*[θ], including whatever information relates it to *ba*[ðz].

In sum, an understanding of so-called analogy depends on a difference in the nature of the lexical representations of the two grammars. Such an explanation relies on careful analysis of diachronic change, with due appreciation for the nature of grammar and the nature of the acquisition process, including

real-time processing, subject to priming effects and other nongrammatical processing.

Morphological Typology

C Iacobini, Università di Salerno, Salerno, Italy

© 2006 Elsevier Ltd. All rights reserved.

At the beginning of the 19th century, linguistic typology established a small set of types, i.e., isolating, agglutinating, fusional (*see* 'The Fusional Type,' 'The Agglutinating Type,' and 'The Isolating Type' below), to which any single language could be assigned. The main criteria for the assignment were related to word structure.

For a long time, word structure remained the dominant criterion to classify languages into types, so that morphological typology is sometimes defined as classical typology as well.

Friedrich Schlegel (1772–1829) and his brother August Wilhelm (1767–1845), together with Wilhelm von Humboldt (1767–1835) – who was also the first scholar who identified the polysynthetic type (*see* **Polysynthetic Language: Central Siberian Yupik**) – gave the most important contribution to the assumption that it was possible to describe the whole grammatical structure of a language starting from the way in which relational concepts are morphologically encoded (following suggestions from contemporary research in botany and paleontology).

With Edward Sapir (1921) there was an important shift within morphological typology. Abandoning the holistic approach, he underlined the internal inconsistencies of the classical schema of classification, and distinguished and made explicit the relevant parameters for classification. According to Sapir, it is possible (and usual) for the same language to show morphological structures belonging to more than one type.

Modern linguistic typology – which arose with the work of Joseph Greenberg (1966) – attempts to classify languages simultaneously on several dimensions, using implicational types of relations to establish limitations on the range of possible variation occurring within linguistic structures. Therefore, morphology is no longer seen as the most fundamental form of language classification, but one of the main levels in which languages can be described.

In contemporary typology, the classification by morphological types is mostly a convenient way to rapidly identify some morphological characteristic of languages, but it is marginal both in theoretical and descriptive studies.

If compared with those of the beginning of the 19th century, the aims of morphological typology have become more modest. However, the role played by morphology in the research of possible patterns of co-variation and correlation with other levels of linguistic analysis is still very relevant today.

Morphological Types

The classification of languages by morphological types is still today part of the standard terminology of linguistics. However, it is also strongly criticized by the majority of typologists for three main reasons:

1. the classification criteria are rather vague and difficult to apply in a consistent way;
2. the morphological type is defined in terms of mutual favorability of properties rather than of implicational correlations, resulting in a low predictive power;
3. morphological typology has a holistic background.

Another reason for criticism comes from the emotive appeal of linguistic imperialism: modern linguistics has disavowed the ideological prejudice dating back to the beginning of the 19th century, according to which the fusional morphological type was considered superior to other types both on a functional and on an evolutionary scale (the presumed superiority stemmed from scholars' Western-centered standpoint: in fact, all the older and many of the contemporary Indo-European languages can be classified as fusional).

There are three fundamental conceptions of language type based on morphological criteria:

real-time processing, subject to priming effects and other nongrammatical processing.

At the beginning of the 19th century, linguistic typology established a small set of types, i.e., isolating, agglutinating, fusional (*see* 'The Fusional Type,' 'The Agglutinating Type,' and 'The Isolating Type' below), to which any single language could be assigned. The main criteria for the assignment were related to word structure.

For a long time, word structure remained the dominant criterion to classify languages into types, so that morphological typology is sometimes defined as classical typology as well.

Friedrich Schlegel (1772–1829) and his brother August Wilhelm (1767–1845), together with Wilhelm von Humboldt (1767–1835) – who was also the first scholar who identified the polysynthetic type (*see* **Polysynthetic Language: Central Siberian Yupik**) – gave the most important contribution to the assumption that it was possible to describe the whole grammatical structure of a language starting from the way in which relational concepts are morphologically encoded (following suggestions from contemporary research in botany and paleontology).

With Edward Sapir (1921) there was an important shift within morphological typology. Abandoning the holistic approach, he underlined the internal inconsistencies of the classical schema of classification, and distinguished and made explicit the relevant parameters for classification. According to Sapir, it is possible (and usual) for the same language to show morphological structures belonging to more than one type.

Modern linguistic typology – which arose with the work of Joseph Greenberg (1966) – attempts to classify languages simultaneously on several dimensions, using implicational types of relations to establish limitations on the range of possible variation occurring within linguistic structures. Therefore, morphology is no longer seen as the most fundamental form of language classification, but one of the main levels in which languages can be described.

In contemporary typology, the classification by morphological types is mostly a convenient way to rapidly identify some morphological characteristic of languages, but it is marginal both in theoretical and descriptive studies.

If compared with those of the beginning of the 19th century, the aims of morphological typology have become more modest. However, the role played by morphology in the research of possible patterns of co-variation and correlation with other levels of linguistic analysis is still very relevant today.

Morphological Types

The classification of languages by morphological types is still today part of the standard terminology of linguistics. However, it is also strongly criticized by the majority of typologists for three main reasons:

1. the classification criteria are rather vague and difficult to apply in a consistent way;
2. the morphological type is defined in terms of mutual favorability of properties rather than of implicational correlations, resulting in a low predictive power;
3. morphological typology has a holistic background.

Another reason for criticism comes from the emotive appeal of linguistic imperialism: modern linguistics has disavowed the ideological prejudice dating back to the beginning of the 19th century, according to which the fusional morphological type was considered superior to other types both on a functional and on an evolutionary scale (the presumed superiority stemmed from scholars' Western-centered standpoint: in fact, all the older and many of the contemporary Indo-European languages can be classified as fusional).

There are three fundamental conceptions of language type based on morphological criteria:

1. the classical (cf. Schlegel, 1808): each type is distinguished from the others in a clear-cut way and is characterized by the presence/absence of one single feature (e.g., languages with or without inflection);
2. the continuum (cf. Sapir, 1921): each type shares with the others a combination of various features, each of them having a continuum of values with two well-defined ends; the structures of a language can be placed on a specific point along the axis anchored by each feature;
3. the ideal (cf. Skalička, 1966): each type is an ideal model (which is never fully realized), consisting of a set of features which tend to co-occur.

According to the last conception, each morphological type may be described as a combination of functionally interconnected features, which, as a whole, form an ideal construct characterizing (the whole, or some aspects of) the morphology of languages (Sgall, 1995). Languages are rarely pure types; they usually mix elements of different types. Assigning a language to a specific type depends on the preponderance of features considered significant (the quantification of such features is a difficult problem to solve from a practical point of view).

Criticism of Morphological Types

The vagueness of the classification in morphological types is shown by the lack of consensus on the number of both types and parameters identifying them. The three main types are: fusional, agglutinating, and isolating. There is no agreement either on whether the polysynthetic type should be considered autonomous or an extreme degree of the agglutinating one (*see* **Polysynthetic Language: Central Siberian Yupik**), or on whether Semitic language features are sufficient to distinguish an introflecting type from the fusional one.

The classical morphological typology only referred to the formal encoding of single morphological features. Sapir (1921: Chap. 6) recognized the shortcomings and contradictions of the 19th century typologists, and, in modern linguistic terms, made explicit the formal components implicit in previous proposals. He adopted a multidimensional approach to morphological typology that could integrate different dimensions of classification, among which the semantic content of morphological expression as well. He distinguished three main criteria of classification:

1. morphological technique: isolating, agglutinating, fusional, symbolic (internal modification);
2. index of synthesis: analytic, synthetic, and polysynthetic structures;
3. how relational concepts are expressed (making a distinction on whether they are expressed through lexical bases or relational elements), and the degree of grammaticalization of relational concepts.

With Sapir, there is a move from a taxonomic criterion according to which each language has to be ascribed to one type, to a classifying criterion based on possible types of morphological structures, in the definition of which semantics plays an important role as well. Moreover, it is explicitly recognized that a language can be classified into more than one type, and that types shade one into the other.

Greenberg (1954) elaborated Sapir's proposal with the aim of applying it to quantitative evaluations on the morphology of different languages.

The three parameters that are nowadays mostly used for the typological classification of languages are the ratio of morphs to word forms, the number of morphemes to morphs, and the degree of word-internal modification of morphs. The first parameter distinguishes analytic from synthetic languages; the other two distinguish, within the synthetic group, agglutinating from fusional languages.

Lists of Clustering Features

The best-known attempt to establish a list of features that co-occur in morphological types is the one made by Skalička (1966), which also includes aspects of word phonology and word order. In the following sections, the features of the three main types (agglutinating, fusional, and isolating) will be given (*see also* **Finnish as an Agglutinating Language**; **Italian as a Fusional Language**; **Chinese as an Isolating Language**), with the reminder that whereas the final ends of some dimensions can be reached, others are unlikely or impossible to reach. The analysis and discussion of polysynthetic and introflecting types is carried out in sections devoted to them (*see* **Polysynthetic Language: Central Siberian Yupik**; **Arabic as an Introflecting Language**). Suffice it to say here that whereas the polysynthetic type presents a variety of forms and is spread in a lot of languages, the introflecting type is not widely spread and, even in those languages where it is found, it is restricted to a part of morphology.

The features that tend to cluster in languages displaying one of the three main morphological types can be listed as shown in the following sections.

The Fusional Type

1. Words are formed by a root and (one or more) inflectional affixes, which are employed as a

primary means to indicate the grammatical function of the words in the language. Agreement is widely employed.
2. High degree of modification of internal morph boundaries, with a consequently difficult linear segmentation.
3. Tendency to cumulate morphological meanings in a single affix (with consequent asymmetry between the semantic and formal organization of grammatical markers).
4. Word-class distinction is maximal. Inflection is rich, as regards both the number of inflectional classes and the extension of paradigms.
5. Stem suppletion; many cases of both homonymy and synonymy among affixes; clear distinction between inflectional and derivational affixes.
6. A slight correlation with syntax can be seen in the relatively free word order (but there are also fusional languages with a fairly fixed word order).

The Agglutinating Type

1. Words are formed by a root and a clearly detachable sequence of affixes, each of them expressing a separate item of meaning. Affixes are widely employed to indicate the relationships between words. Therefore, there are few or no independent relational elements (e.g., pronouns, pre-/postposition, articles, etc.), and a wide use of nominal cases.
2. Very high matching between morphs and morphemes. Morphs are loosely joined together; consequently it is very easy to determine the boundaries between them.
3. Each affix carries only one meaning: no cases of homonymy or synonymy among affixes; the semantic structure is directly reflected in the morphological articulation of the word; no principled limits to the number of affixes in a word.
4. Word-class distinction is minimal: the same affixes tend to occur with roots belonging to different parts of speech (e.g., personal endings to nouns, case endings to verbs); almost the same morphology for adjectives and verbs. No inflectional classes, no gender distinction.
5. Derivational affixes are widely employed in word formation. The distinction between inflectional and derivational affixes is slight. Many affixes reveal their lexical origin to some extent. The latter feature, together with the tendency of affixes to form autonomous syllables and to be relatively unconstrained in number, results in words that are quite long.
6. Relatively fixed word order. Agreement is almost completely absent.

The Isolating Type

1. Words are monomorphic, invariable, and formed by a single root. Ideally, bound forms are completely missing. Position is the main way of expressing the relationship between independent words.
2. Relational meanings are not overtly expressed, or the same units that normally encode lexical concepts are used for that purpose as separate helper words; the meaning and function of a word considerably depend upon the syntagmatic context.
3. There is little to no morphological complexity. Morphs are clearly identifiable both phonologically and semantically: morph boundaries are sharply defined, phonological form is invariant, there are no instances of overlapping exponence. Derivation is nonexistent, partly replaced by compounding.
4. The distinction in parts of speech is not clear; there is no overt expression of grammatical categorization.
5. Tendency to monosyllabism with no phonetic distinctions between the elements expressing lexical meaning and the ones expressing relational meaning.
6. Rigid word order.

Comparison

The fusional type is differentiated from the isolating type by the use of bound morphs and the clear-cut distinction between word classes; it is differentiated from the agglutinating type by the kind of juncture between morphs, and the nonbiunivocal correspondence between morphs and morphemes. In the synthetic vs. analytic distinction, the fusional and even more the agglutinating type tend toward the synthetic end.

Types characterization can be schematically summed up in Table 1.

Contemporary Morphological Typology

In spite of criticism, the classification by morphological types is still convenient and widely used in order to rapidly identify a number of features that tend to co-occur in the morphology of a language. Some authors also use it to assess the extent to which a language moves away from such ideal constructs both in a synchronic and in a diachronic perspective (Dressler, 1985 argues that languages tend to move toward a typological goal according to a linguistic economy criterion; *see* **Natural Morphology**).

On the contrary, the classification by morphological types is now negligible in contemporary

Table 1 Features characterizing fusional, agglutinating, and isolating types

	1	*2*	*3*	*4*	*5*	*6*	*7*	*8*	*9*	*10*	*11*	*12*	*13*	*14*
Fusional	Yes	No	No	Yes	No	No	No	Yes	Yes	Yes	Yes	Yes	No	Yes
Agglutinating	Yes	Yes	Yes	No	No	Yes	No	Yes	Yes	No	No	Yes	No	No
Isolating	No	Yes	Yes	No	Yes	Yes	Yes	No	No	No	No	No	Yes	No

(1) affixes; (2) word function determined by position; (3) possibility of segmentation (morph-morpheme correspondence); (4) clear-cut distinction in part-of-speech; (5) tendency to monosyllabism; (6) fixed syntactic order; (7) syntagmatic structures employing particles; (8) noun marked for number; (9) noun marked for case; (10) noun marked for gender; (11) adjectives expressing agreement; (12) synthetic expression of comparison on adjectives; (13) verb: use of analytic structures (vs. affixes); (14) verb: presence of inflectional classes.

typological research, since scholars do not expect the morphological type to correlate in a significant way with other typological parameters. As they refuse the possibility of classifying the whole of a language into a given type, typologists pay increasing attention to the practice of partial typology, focusing on specific areas of linguistic structure (Bynon, 2004). Partial typology analyzes clusters of properties with a view to ascertaining significant connections and hierarchical organization. The main tool for analysis is establishing implication universals according to Greenberg's (1966) suggestions. However, disregarding morphological types does not result in the death of morphological typology: almost half of Greenberg's 45 universals concern morphology. These universals mainly focus on two aspects previously neglected by morphological typology:

1. the relative order in which (derivational and inflectional) concepts are expressed morphologically within word forms;
2. the hierarchy of concepts which a language expresses morphologically.

Examples of the first are universals 28 and 39. The former states that if derivational and inflectional affixes are on the same side of the root, then the derivation is always closer to the root. The latter says that in a noun the expression of number is nearly always closer to the base than the expression of the case. Examples of the second are universal 36 'If a language has the category of gender, it always has the category of number,' and 37 'A language never has more gender categories in nonsingular numbers than in the singular.'

While it is true that only with Greenberg (1966) does syntax start to play a major role in typology, it is to be said that even the famous syntactic universals concerning word order (e.g., universals 3 and 4, which relate VSO order with preposition, and SOV order with postposition) show a link with morphology, for example, via universal 27 (which relates suffixing and postpositional languages on the one hand and prefixing and prepositional languages on the other). Another example is universal 41, which states the implication between the SOV word order and the presence of a case system. Because of such a link, morphology has acquired importance for scholars interested in word order typology. There are many studies that associate the use of suffixes or prefixes with OV and VO order, respectively (see Cutler *et al.*, 1985; Hawkins and Cutler, 1988; Hawkins and Gilligan, 1988, where affix preference is related with head position and also explained by psycholinguistic factors; see Bybee *et al.*, 1990 for a diachronic approach; Dryer, 1992, who attempts to integrate different approaches).

At the interface between morphology and syntax there are works such as Nichols (1986), which distinguishes head- and dependent-marking, and others, such as those dealing with the morphologically based typology of causative constructions.

Greenberg (1966) barely takes into account phonology. However, the Universals Archive (cf. Plank and Filimonova) collects some universals concerning the interaction between morphology and phonology. Examples are universal 219 stating that affixes have a more limited inventory of phonemes than roots and universal 713, which correlates agglutinative morphology with vowel harmony, and fusional morphology with stress accent.

As far as morphology itself is concerned, the main effect of Greenberg's typology has been to stimulate the investigation of implicational relations between morphological categories, to promote the study of the markedness (overt expression) of morphological values, as well as the investigation of the reasons for the greater or lesser closeness of relational morphemes to the lexical base, and of the role played by morphological heads.

One of the main problems that stands before morphological typology is to identify a phenomenon as the same thing in different languages, since the values of one grammatical category may be expressed morphologically in some languages and in a different way in others. Cross-linguistic identification on purely formal criteria is not far-reaching (an example is

Greenberg' universal 26: 'If a language has discontinuous affixes, it always has either prefixing or suffixing or both'); on the other hand, purely functional statements are not sufficient, because, by definition, they need a formal counterpart to be morphological. This type of difficulty explains why studies on inflectional morphology are overwhelmingly prevailing over derivational ones: categories such as case, gender, and number are cross-linguistically better identified and defined (see Blake, 2001; Corbett, 1991, 2000) than derivational ones; furthermore, the internal articulation of inflectional categories, featuring a number of values within one category (e.g., singular, plural for number), favors cross-linguistic comparison within the inflectional domain. The study of the variation in the expression of derivational categories is certainly more difficult and much remains to be done; see Bauer (2002) for a recent attempt.

Morphological Universals

Overview

Morphological universals are generalizations about the morphological structure of a possible human language. Languages differ radically as to the properties of their morphological systems, but this variation is not unlimited: certain morphological patterns are not attested in any language, and morphological universals are explicit statements that impose restrictions on cross-linguistic variation in the domain.

Because all theories of morphology (e.g., natural morphology, lexical phonology, a-morphous morphology, distributed morphology, prosodic morphology, to mention only a few) deduce predictions about what morphological properties cannot occur in natural language, any such theory is associated with its own set of

morphological universals, even if not recognizing the notion of universal explicitly. But morphological frameworks differ substantially as to their basic assumptions, descriptive and analytic tools, and theoretical primitives. As a result, morphological universals recognized within different frameworks are highly theory bound. For example, a theory assuming that words and word forms (at least to some extent) are built in the syntax and are transparent to rules and principles that operate at the phrasal level (e.g., Halle and Marantz, 1993), is expected to produce less purely morphological universals than a strict lexicalist theory, which assumes that words are created presyntactically. A theory whose primary concern is the meaning of grammatical (and, in particular, morphological) items (e.g., grammaticalization theory) is unlikely to recognize universals about noun incorporation. A theory exploring the interaction of prosodic structure and morphological structure (e.g., prosodic morphology) has very little to say about possible patterns of case syncretism, and so on. Furthermore, what is recognized as a universal in one theory can be theoretically impossible in another theory (or even in the same theory at the later stage of its development). For instance, Jelinek (1984: 74) puts forward the generalization that syntactically nonconfigurational languages (those possessing a flat syntactic structure) are agglutinative. Evidently, this generalization is only valid as long as nonconfigurationality is recognized as a theoretical possibility. Because later on nonconfigurationality was abandoned by generative grammar in favor of strict binary branching enforcing a hierarchical structure, no room was left for Jelinek's generalization.

Therefore, the whole inventory of morphological universals, if thought of as a union of all sets of theory-internal universal statements, is extraordinarily huge and, given that the number of possible linguistic theories is not restricted, potentially infinite. Furthermore, as we have just seen, this inventory may contain incompatible or even controversial statements.

For this reason, a more restricted notion of morphological universal is commonly assumed. In a narrow sense, morphological universals are those generalizations about morphological structure that are established within Greenbergian tradition of linguistic theorizing (see Greenberg, 1963, universals 26–45). These generalizations are essentially inductive, rather than deductive: formulating universals that capture various properties of morphological items and processes precedes explanation and constitutes a necessary condition for it. Universals can only emerge as a result of cross-linguistic study, in which representative samples of natural languages are taken into account. This contrasts sharply with many other linguistic frameworks where generalizations are deduced on purely theoretical grounds and only after that are tested against cross-linguistic data.

At present, morphological universals seem to be less systematically documented than phonological and syntactic ones. The Konstanz Universals Archive (KUA, Plank and Filimonova, 2002), the most complete and systematic collection of information on natural language universals on which this article relies heavily, contains about 2000 records, and only about 150 of them are filed under the rubric 'morphology' (although a number of relevant universals are also listed under the rubric 'inflection'). In what follows, I will review main universals about a possible shape of morphological items and their meaning/function. The concluding section surveys possible ways of explaining morphological universals.

A Possible Structure of Morphological Items

One of the most familiar universals, frequently referred to in the literature, captures the implicational relation between affixation and nonconcatenative morphology. It claims that if there is internal stem modification or suprasegmental modification or subtraction or conversion or suppletion in derivation or inflection, then there is affixation. This universal allows languages in which affixation and other types of derivational and/or inflectional morphology are absent altogether (Vietnamese is frequently cited as an example), languages in which both occur (e.g., English) and languages that only make use of affixation (e.g., Turkic). It rules out the fourth possibility, e.g., languages with stem alternations but without prefixes/suffixes. A closely related observation (Greenberg's, 1963, universal 26) says that if there are discontinuous affixes, then there is prefixing and/or suffixing.

As far as affixes are concerned, natural languages tend to have suffixes rather than prefixes. Various manifestations of this tendency have been cited in the literature. Thus, Hall (1988) observed that only 4% of languages that have affixes are exclusively prefixing, and 41% of such languages are exclusively suffixing. Moreover, whether languages have prefixes, suffixes, or both correlates with the order of constituents in the syntax. Greenberg's (1963) universal 27 states that exclusively suffixing languages are prepositional whereas exclusively prefixing languages are postpositional. If the VO/OV order is taken into account, one can observe that exclusive prefixing does not occur in OV languages at all, whereas about 64% of such languages are exclusively suffixing. VO languages are more tolerant to prefixation: 72% have prefixes and suffixes, about 9% are exclusively

prefixing, and only 19% are exclusively suffixing. Hawkins and Cutler (1988) surveyed implicational relations between prefixing/suffixing and basic word order for the exponents of 11 inflectional categories: gender, case, indefiniteness, nominalization, definiteness, plurality, mood, tense, aspect, valence, and causative. In particular, they observed that there are no prefixal exponents of gender and indefiniteness in OV and postpositional languages, whereas case marking is suffixing rather than prefixing regardless of the basic word order.

Another manifestation of prefixation/suffixation asymmetry is that there is more prefixing on verbs than on nouns. If a language has any prefixes on nouns, it will also have prefixes on verbs with considerably more than chance frequency. Thus, there are languages that only have suffixes on both nouns and verbs, languages that have prefixes on both nouns and verbs, and languages with verbal prefixation but without nominal prefixation. An example of the latter type is Darghi (North-Caucasian) in which a verb can take up to four prefixes indicating agreement, location, movement with respect to the speaker, and movement with respect to a landmark other than the speaker (e.g., *či-j-ka-w-qid* 'dismount, get off (the horse)', where *qid* is a stem 'go', *w* is a masculine singular agreement marker, *ka* indicates movement upside down towards the speaker, *ĉi* – location on the surface of the landmark and *j* – movement from the landmark). Yet, nominal prefixation in Darghi is not attested at all.

Another type of morphological generalizations about the shape of morphological items relates various aspects of their phonological structure to the celebrated classification of languages as isolating, agglutinating, fusional, and incorporating. In particular, it has been observed (especially within natural morphology framework, see, e.g., Dressler, 1985) that if morphology is flexive, word forms tend to be two or three syllables long, whereas if morphology is agglutinating or incorporating, word forms tend to be longer. Trivially, if a language is isolating, that is, lacking bound morphology, word forms are shorter. Polysynthesis implies that consonant–vowel ratio is comparatively high. Agglutinating morphology implies simplicity of syllable structure, and higher syllable-per-sentence and syllable-per-word ratios than flexive morphology. At the same time, derivational affixes show more phonological complexity in agglutinating languages than in flexive languages. Although generalizations of this type do capture significant asymmetries found in the data, they seem to be problematic given the vagueness of the very notion of agglutinating vs. flexive languages. Recent work has shown that agglutination should not be viewed as a primitive notion but rather as a family of related but logically independent morphological parameters such as separatist vs. cumulative exponence and invariant vs. variant exponence (Plank, 1999); furthermore, it has been shown (Haspelmath, 2000) that values of these parameters exhibit no statistically significant correlation (thus, e.g., Nivkh (isolate) shows a high degree of cumulation but virtually no multiple exponence, while Ponapean (Oceanic) demonstrates a great deal of stem alternation but virtually no cumulation). As a result, the empirical validity of the above-mentioned generalizations can only be verified if such notions as 'agglutinating' or 'flexive' are made more precise.

Bybee (1985) makes significant cross-linguistic generalizations about the distribution of inflectional and derivational morphological items. Having examined verbal morphology across 50 languages, she proposed that derivational/inflectional status of morphological items correlates with their semantic relevance for the root and generality of their meaning. The degree of relevance is determined by the extent to which morphological items modify the semantic content of the root; generality suggests that a morphological item applies consistently to the vast majority of roots and yields the same semantic effect. The more relevant, the meaning of a category is for the meaning of the root, and the less general it is, the higher is the probability that it is expressed derivationally. The opposite holds for inflectional morphology. Thus, causative morphemes tend to be derivational, because they affect the argument structure of a verb, whereas tense morphemes are normally inflectional, because they only relate a situation referred to a deictic centre without changing the number of its participants. Furthermore, the concept of relevance accounts not only for the inflectional or derivational status of morphemes, but also for their relative order (cf. Greenberg's, (1963) universal 28): derivational items (e.g., causative morphemes) occur closer to the root than inflectional ones (e.g., tense and aspect morphemes) because of their high semantic relevance (a possible counterexample is Navajo and other Atapaskan languages). Clearly related to Bybee's observations is Greenberg's (1963) universal 39, which states that if morphemes of both number and case are present and both follow or precede the noun base, then the exponent of number 'almost always' comes between the noun base and the exponent of case (cf., e.g., the genitive plural *malaj-lar-niŋ* || **malaj-niŋ-lar* 'of the boys' in Tatar (Altaic)). If plurals are more relevant to a nominal stem than case markers, because they affect its reference properties, this ordering is again expected.

Bybee has been frequently criticized for not providing a precise definition of relevance. Alternative,

strictly structural, explanation of the morpheme order involves Baker's (1985) mirror principle that states that the order of morphemes mirrors the sequence of functional projections above the verbal projection. However, this approach relies crucially on the assumption that words and word forms (at least to some extent) are built syntactically and can hardly be implemented within lexicalist frameworks assuming a presyntactic word-formation component of the grammar. Another structural account for the relative order of inflectional and derivational morphemes is offered in Anderson (1992). Anderson suggested that whereas derivation occurs in the lexicon, inflection is part of the syntax, and rules of the syntactic component applies after lexical rules. Given this architecture of grammar, Greenberg's universal 28 and similar generalizations.

Universal restrictions on phonological structure of morphological items frequently reveal themselves in templatic morphology. Consider reduplication as an example. The reduplicant is commonly thought of as an affix that does not have a fixed segmental content, but provides a template to which segments are copied from the base. Moravcsik (1978) suggests that the shape of the reduplicant is constrained by the following universal: there is no reduplication pattern that involves reference to phonological properties other than syllable number, consonantality-vowelhood, and absolute linear position. The further elaboration of this generalization is provided by prosodic morphology theory (McCarthy and Prince, 1986 *et seq.*), which hypothesizes that all templatic requirements on varying segmental material are defined in terms of prosodic units – mora, syllable, foot, and prosodic word. Thus, in Ilokano (Austronesian) a reduplicative template for nominal plurals is a heavy syllable (*kaldíŋ* 'goat' – *kal-kaldíŋ* 'goats', *róʔot* 'litter' – *ro:-róʔot* 'litters'; in the latter case, because glottal stops cannot occur as codas, it is not copied from the base, but the vowel *o* is lengthened instead to meet templatic requirements), while in Diyari (Australian) it is a minimal prosodic word consisting of a bisyllabic trochaic foot: *tʲilparku—tʲjilpa-tʲjilparku* 'bird species'. Although there are debates as to whether reduplication is templatic in all languages, to the extent it is templatic the crucial generalization is that templates are never defined in morphological or linear terms (e.g., 'copy the first morpheme', 'copy the last three segments', and so on.)

Prosodic considerations play an important role in answering the question of whether infixation should be universally recognized as a special type of affixation. Recent studies (McCarthy and Prince, 1993), implemented within optimality-theoretic framework, have shown that at least many instances of infixation can be reduced to suffixation/prefixation to a phonologically defined prosodic unit located within the morphological unit. Possessive markers in Ulwa (Misumalpan) are attached after the first foot of the root, so that they are suffixed if a root contains just one foot (e.g., *sana-ka* 'his/her deer') and infixed in roots that are longer than one foot (e.g., *kulu-ka-luk* 'his/her woodpecker'). In Tagalog (Austronesian), the actor topic morphemes *-um-* is prefixed to vowel-initial roots, but infixed in consonant-initial roots to avoid onsetless syllables whenever possible. Ultimately, these generalizations led to a more spartan conception of affixation whereby only prefixes and suffixes are recognized as possible affixes cross-linguistically.

Although universals and universal-like generalizations discussed so far mostly involve morphology proper as well as morphology–phonology interface, further universal generalizations emerge at the morphology–syntax interface. Thus, widely discussed are incorporation phenomena, and, in particular, noun incorporation. Mithun (1984) observes regular cross-linguistic asymmetries as to what types of nouns can undergo incorporation: if patients of intransitive verbs can be incorporated, patients of transitive verbs can also be incorporated. Baker (1985) provides a syntactic explanation of the observed asymmetries in terms of government and binding theory. On his analysis, noun incorporation is a head movement that adjoins a noun to a verbal head provided that the latter properly governs the former. The latter condition, a manifestation of the general head movement constraint adopted within government and binding theory, predicts, correctly, that only material governed by the verbal head (objects of transitives and subjects of unaccusatives) can incorporate. It is only possible to move the lower lexical item, the noun, in order to combine with the higher lexical item, the verb. Crucially, this is not a theoretical possibility for agents of transitives and unergatives, which are base generated above the verb and not c-commanded (and hence governed) by it. Under this analysis, incorporation of such nouns, which is attested in, e.g., Mayali (Australian), can only be analyzed as involving lexical compounding. Alternative approaches to the noun incorporation suggest (see, e.g., Rosen, 1989) that in fact all instances of incorporation are purely lexical and its distribution is to be captured in semantic rather than syntactic terms. But whether either of these approaches can be proved to hold for all languages still remains to be seen.

Possible Functions of Morphological Items

A bulk of morphological universals impose restrictions on inventories of inflectional and, less frequently,

derivational categories, thus determining a possible number, gender, case, tense-mood-aspect system, etc. Frequently, these generalizations take form of hierarchies whereby existence of a morphological exponent for a category C entails existence of morphological exponents for categories dominated by C. For instance, Greenberg's (1963) universal 34 suggests the following number hierarchy: singular < plural < dual < trial. According to this hierarchy, for example, if a language possesses a morphological exponent for the trial number, it also possesses those for the dual, plural, and singular numbers (Yimas (Sepic-Ramu) is an example of such a language).

Other grammatical categories and their morphological exponents show much the same behavior. Thus, the masculine gender is dominated in the hierarchy by the feminine gender, which is in turn dominated by the neuter gender, pronominal person systems are constrained by the hierarchy 1, 2 person < 3 person; comparative and superlative degrees expressed on adjectives entail that adjectives have also a positive degree, the passive voice entails the active one, and the hypothetical mood entails the indicative.

Corbett (1991) and Dahl (1999) explore gender assignment systems cross-linguistically. The main finding of these studies is that the gender of the vast majority of nouns can be predicted from the information (semantic, morphological, and phonological) required independently in the lexicon (Corbett, 1991: 68). Furthermore, the gender is never assigned according to phonological or morphological properties of nouns (e.g., declension class) exclusively: there is always a general semantically based principle for assigning gender to animate nouns, whereas individual languages vary as to where the cutoff point between semantic and morphological/phonological assignment is located at the animacy hierarchy. In Tamil (Dravidian), for example, there are separate genders for male humans and female humans; everything else is assigned to a third gender. In many Indo-European languages, humans and also, to a varying extent, higher animals, are assigned masculine or feminine gender on the basis of their sex, whereas inanimates and lower animals get their genders by lexeme-specific or formal criteria.

Cross-categorical implicational relations are also well attested. A frequently cited example is provided by Greenberg's (1963) universals 30 and 36. The first states that if the verb inflects for person-number or for gender, then it also inflects for tense-mood. The second establishes the implicational relation between gender and number: if a language has a category of gender it always has a category of number. Another example is Greenberg's universals 37 and 45 discussed in Plank and Shellinger (1997): a language never has more gender categories in nonsingular numbers than in the singular. This universal turns out to be statistical rather than absolute: for instance, Hadza (Khoisan) distinguishes between first person plural masculine and feminine (*o(ne)bi* vs. *obe*) while using the same pronoun in the singular (*эno*).

Typological studies of tense and aspect systems reported in Dahl (1985) and Bybee *et al.* (1994) reveal a new trend in the analysis of the universal properties of grammatical items. Rather than establishing a set of implicational universals about the meaning and distribution of tense and aspect morphemes, Bybee and Dahl identify what they call cross-linguistic gram types (CGTs), that is, clusters of semantic properties that tend to be expressed grammatically in genetically and areally unrelated languages and possess their typical morphosyntactic means of expression. Verbal forms that constitute tense-mood-aspect systems of individual languages are manifestations of CGTs. For example, the CGT *past* is characterized by its meaning ('a situation occurs before the moment of speech') and form (inflectional expression), and its manifestation in English is Simple Past verb forms. The crucial assumption within this approach is that a restricted set of CGTs defines the structured universal grammatical space from which individual languages choose available possibilities to develop their grammatical systems. Besides, CGTs come into existence by a restricted set of paths of diachronic development. For example, perfects can only emerge from resultatives and through the grammaticalization of lexical items like 'finish' or 'already' and can only develop into the past perfective or indirect evidence grams. Generalizations like these impose additional restrictions on both the inventory of grammatical items in individual languages and on the meaning and distribution of individual grammatical morphemes. The question of how many cross-linguistic gram types are there is still debated: Dahl (1985) identified about 20 CGTs, whereas Bybee *et al.* provide a more extended list containing about 40 items.

Another type of cross-linguistic generalization determines minimal inventories of grammatical distinctions. Thus, Comrie (1985) observes that tense systems in natural languages minimally provide a two-way distinction between past and nonpast temporal reference (e.g., Finnish), whereas no systems differentiating between present and nonpresent or future and nonfuture temporal reference are attested.

Various universal lexical restrictions on the distribution of grammatical morphemes are attested cross-linguistically. In a few languages only nouns denoting people show plural number marking. This observation is captured by Corbett's (2000: ch. 3) generalization that if a language has plural forms of nouns at all,

it will have plural forms of nouns denoting people. In the WALS sample (Haspelmath, 2005) containing 290 languages the majority (133) possess obligatory plural marking in all nouns, 28 languages lack plural marking altogether, in 59, plural marking is restricted to human nouns, either optionally, as in Hatam (West Papuan; Indonesia), or obligatorily, as in Jamul Tiipay (Yuman; southern California). In 15 languages (e.g., Arawak (Arawakan; Suriname)) plural marking is obligatory in human nouns and optional in inanimate nouns. Crucially, no languages are attested where plural, either optional or obligatory, occur only in inanimate nouns, nor languages in which plural marking is compatible with all nouns, but only optional in human nouns.

A common lexical restriction within tense-mood aspect domain is incompatibility of the progressive marking with stative (e.g., 'see'), especially individual-level (e.g., 'like'), verbs. Another example of lexical asymmetry is frequently attested systems in which the same verbal form can have different interpretation depending on a lexical class of a verb. In such systems, the atelic/stative verbs yield imperfective/present interpretation, whereas telic verbs are associated with the perfective reading, either past (e.g., Tundra Nenets (Uralic)) or future (e.g., Russian).

Because grammatical morphemes are normally multifunctional, an important area of cross-linguistic research are universal constraints on grammatical polysemy. For example, the dative case in Tatar (Altaic) can express, among other things, the recipient semantic role and the direction of movement, while in Russian only the former meaning of the dative is available. Therefore, the general question is what are universal constraints on how meanings can be combined within the same grammatical morpheme. Recently, a number of such constrains have been identified in a few areas of grammatical semantics.

An area in which cross-linguistic generalizations are still to be found includes syncretism and blocking phenomena. Syncretism is the correspondence of a single inflected word form to two or more sets of morphosyntactic features defining a cell in the morphosyntactic paradigm. In English, an instance of syncretism is verb forms such as *hit*, identical for the simple present and simple past, which are distinguished by the overwhelming majority of other verbs. In Russian, the dative singular (e.g., *mashin-e* 'to the car') is identical to the locative singular (*(v) mashin-e* 'in the car') for all nouns of a particular morphological class. Cross-linguistic patterns of syncretism are extremely diverse. The Surrey Syncretisms Database (Baerman *et al.*, 2002) lists about 70 case pairs in 30 languages that share the same fully inflected forms (e.g., ablative/ergative, accusative/genitive, etc.), more than 60 number pairs, more than 50 person pairs, more 30 tense pairs, and so on. Various attempts have been made to find out constraints on syncretism. For example, Carstairs-McCarthy (1998) formulated four principles that restrict a possible morphosyntactic content of inflectional affixes. These are the Principle of Contrast (every two affixes contrast in meaning); Exclusive Disjunction Bar (the meaning of an affix cannot contain a disjunction of incompatible morphosyntactic properties, e.g., 'past' or 'future', 'instrumental' or 'dative'); Complementarity Bar (the meaning of an affix cannot be specified negatively, as 'nonpast' or '–2nd person'), and Unmarked Property Bar (the meaning of an affix cannot contain specific mention of the least marked value of a feature, e.g., 'present', 'indicative' or 'singular'). Additionally, Carstairs-McCarthy assumed the Elsewhere Condition: if two distinct affixes are compatible with a given morphosyntactic context, the more specific one is preferred. These constraints account for syncretism in Hungarian, Latin, and Turkish, discussed extensively in his study, and, because they do not involve any language-specific assumptions, they can potentially apply to all languages. However, this account (as well as other accounts offered in the theoretical literature, see, e.g., Stump, 2001: ch.7) is to be tested against a wider sample of languages.

The same is true of blocking whereby a possible morphological construction does not occur due to the existence of another, functionally equivalent morphological construction, cf. **mans* vs. *men*, **badder* vs. *worse*, etc. Kiparsky (2005) argued that blocking is a mechanism that resolves the competition between the potential expressions relying on two universal constraints, economy and expressiveness. Economy requires that, other things being equal, the simplest expression be chosen, and expressiveness requires that, other things being equal, all the input meaning be expressed by the output expression. As a result, among equally expressive expressions, the simplest is optimal (this is the reason why *worse* wins over **badder*), and among equally simple expressions, the most expressive one is optimal (this ensures that *bad* is not used instead of *worse*, because *bad* does not express the semantic content of the comparative, thus violating expressiveness). Given the attractive simplicity and restrictiveness of approaches of this type, their universal validity remains to be seen.

Explaining Morphological Universals

Linguistic theories vary sharply not only in what explanatory mechanisms they use in accounting for

cross-linguistic generalizations but even in what they take as explananda.

For formal theories of grammar, particularly, for Generative Linguistics explaining universals is not a (primary) goal; rather, it aims at identifying characteristics of the innate language faculty, Universal Grammar. The primary explanandum is why the acquisition of systematic and structured grammar is possible on the basis of random and non-structured experience ('Plato's problem') and the common assumption is that explanation for universals can be derived directly from the hypotheses about Universal Grammar. In contrast, for functional-typological approaches to language grammatical universals themselves are an ultimate explanatory goal (see Haspelmath (2004) for the extensive discussion).

Functionalists primarily rely on system-external considerations such as frequency, economy, and processing. Haspelmath (2002: ch.12) provides a collection of diverse asymmetries in inflectional categories observed cross-linguistically that can be accounted for in terms of speech frequency. Thus, there is a positive correlation between the frequency of expression and its shortness (cf. Haiman, 1983), which is motivated by the languages users' preference for economical structures: speakers tend to reduce expressions that hearers can predict, and frequent expressions are more predictable and therefore expected by default. This explains why the most frequent words (e.g., articles, prepositions, and conjunctions) are the shortest, why affixes are shorter than roots, why the more frequent inflectional categories cannot be more morphologically marked than less frequent ones, and why the most frequent inflectional categories (e.g., singular, nominative, etc.) can have zero expression (cf., e.g., Greenberg's universal 35: there is no language in which the plural does not have some nonzero allomorphs, whereas there are languages in which the singular is expressed only by zero). In addition, one can observe more syncretism and less suppletive allomorphy in less frequent categories. For instance, in Old Russian verbal conjugation second and third persons were identical in the dual (e.g., *znaj-eta* 'you/they two know' but not in the singular (*znaj-eš* 'you know' vs. *znaj-et*^{j} 'he knows') and plural (*znaj-ete* 'you all know' vs. *znaj-ut*^{j} 'they all know'), and in Latin there were threex suppletive first-person singular endings in the indicative (*amo* 'love', present vs. *amavi*, perfect vs. *amaba**m**,* imperfect) and only one in the subjunctive (*ame**m***, present vs. *amaveri**m**,* perfect vs. *amare**m***, imperfect). Finally, frequency determines the direction of analogical leveling: if analogical leveling occurs, more frequent items tend to replace less frequent ones.

A novel perspective on explaining universal characteristics of human language has been recently developed within Optimality Theory (OT, Prince and Smolensky, 1993). OT relies on the assumption that surface forms of language emerge as a result of resolution of conflicts between universal constraints. All constraints are present in every language and are assumed to be part of our innate knowledge of language. All systematic differences among languages are explained through different constraint rankings. Constraints are ranked with respect to their importance, and each language has its own constraint hierarchy distinct from all others. Constraints are violable, and violations of lower-ranked constraints may be tolerated in order to satisfy a higher-ranked constraint; in this way, the grammar selects an optimal output, which best satisfies the system of ranked constraints.

Within OT framework, universal restrictions on morphological (as well as phonological and syntactic) structure that are not subject to cross-linguistic variation (especially those that take a form of hierarchies) can be captured through the fixed constraint rankings. Aissen (2003) is a particularly straightforward example of this type of analysis. She explored the phenomenon of differential object marking whereby overt case marking of direct objects occurs with some objects, but not with others, depending on their animacy and definiteness. For instance, in Sinhala (Indo-Iranian) only animate-referring objects may be case marked, whereas in Turkish (Altaic) only specific (either definite or indefinite) direct objects receive the accusative case. Aissen proposed two fixed constraint hierarchies (*Oj/Human » *Oj/Animate » *Oj/Inanimate and *OJ/PRO » *OJ/PN » *OJ/DEF » *OJ/SPEC » *OJ/NSPEC) for animacy-sensitive and definiteness-sensitive differential object marking respectively. These constraints penalize the absence of a value for the feature CASE. Additionally, she introduced the constraint *STRUC, which penalizes the specification of morphological CASE. *STRUC can be interpolated at any point in the hierarchies, excluding case marking of all object types in the dominated constraints. Thus, for Turkish *STRUC is located in between *OJ/SPEC and *OJ/NSPEC, effectively eliminating the possibility of case making in nonspecific indefinite objects.

A powerful tool for accounting for universal restrictions on the meaning of grammatical morphemes are semantic maps, which are currently gaining a growing popularity. A semantic map is a connected graph in which nodes are meanings/functions distinguished by grammatical morphemes cross-linguistically. Meanings/functions are arranged on the map in order to meet the adjacency requirement: all

Figure 1 Diachronic semantic map for the resultative, perfect, and related categories.

language-specific grammatical morphemes should occupy contiguous areas on the map, and there must be no language in which a grammatical morpheme is connected to nonadjacent meanings, unless the same morpheme covers all meanings located in between. Due to the adjacency requirement, any semantic map generates a family of implicational universals of the form «If a grammatical morpheme expresses meanings m_1 and m_2, then it expresses meaning(s) m_3, m_4,...» (see Haspelmath, 2003). Semantic maps can be made even more restrictive if symmetric adjacency relations between meanings/functions are replaced by asymmetric paths of diachronic development. Diachronic semantic maps make the same predictions as synchronic ones and, additionally, delimit possible ways of how the meaning of grammatical items can change. Consider perfects as an example. Figure 1 shows a partial diachronic map from Bybee *et al.* (1994) with minor adjustments.

This map allows for a wide variety of languages, both synchronically and diachronically. One of the possible scenarios is represented by the Past forms in East Slavic languages, which are products of diachronic development of the perfect both formally (loss of the auxiliary) and semantically ('perfect' → 'past time reference'). Another development of the same form is attested in Bulgarian (South Slavic), in which the Perfect gave rise to the indirect evidence form. Synchronically, this semantic map predicts, correctly, that no language possesses a grammatical morpheme that can be used, say, in indirect evidence and resultative contexts unless the same form occurs as the perfect. (Such a morpheme is attested in Bagwalal (North Caucasian), where the same verbal form comprises the whole range of uses from the resultative to indirect evidence.) Diachronically, it represents prohibition against violating unidirectionality: the development of resultatives into perfects and so on is irreversible.

Morphologization

B Fortson, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction: Definition of Terms

The term 'morphologization' has had two main uses in historical linguistics: (1) a restrictive one, i.e., the reanalysis of a phonological rule or process as a morphological one, and (2) a less restrictive one, i.e., the reanalysis of any nonmorphological element or process as a morphological one. This latter definition would include various processes that also fall under the rubric of grammaticalization. The difference in usage, coupled with varying understandings of associated terms (like 'grammaticalization'), has led to some confusion. Since much effort has gone into attempts to distinguish the usage, the issue will be briefly treated here at the outset.

The restrictive definition is the traditional one, insofar as classic cases of it like the morphological reanalysis of German umlaut (see below) were the only examples of morphologization that received much attention until more recently. It is the definition still maintained by Klausenburger (1994), who explicitly excluded any kind of grammaticalization from being covered by the term. More commonly nowadays, however, the term is understood in its broader sense, and it is this usage that will be followed here. This usage is also likely to be less confusing, since etymologically there is nothing in the term 'morphologization' to suggest restricting it solely to input from the phonological domain.

While the domain from which the input for morphologization is drawn should not be understood restrictively, matters are different concerning the output. In what follows, it will be understood that the result of morphologization is a genuine morphological change, that is, a change to the morphological component of the grammar. (Terms like 'morphological component' and 'morphological system' will be used here for the sake of convenience and for conceptual purposes to refer to the set of elements and rules used for derivation and inflection. For fuller discussion of the controversies surrounding the

Introduction: Definition of Terms

The term 'morphologization' has had two main uses in historical linguistics: (1) a restrictive one, i.e., the reanalysis of a phonological rule or process as a morphological one, and (2) a less restrictive one, i.e., the reanalysis of any nonmorphological element or process as a morphological one. This latter definition would include various processes that also fall under the rubric of grammaticalization. The difference in usage, coupled with varying understandings of associated terms (like 'grammaticalization'), has led to some confusion. Since much effort has gone into attempts to distinguish the usage, the issue will be briefly treated here at the outset.

The restrictive definition is the traditional one, insofar as classic cases of it like the morphological reanalysis of German umlaut (see below) were the only examples of morphologization that received much attention until more recently. It is the definition still maintained by Klausenburger (1994), who explicitly excluded any kind of grammaticalization from being covered by the term. More commonly nowadays, however, the term is understood in its broader sense, and it is this usage that will be followed here. This usage is also likely to be less confusing, since etymologically there is nothing in the term 'morphologization' to suggest restricting it solely to input from the phonological domain.

While the domain from which the input for morphologization is drawn should not be understood restrictively, matters are different concerning the output. In what follows, it will be understood that the result of morphologization is a genuine morphological change, that is, a change to the morphological component of the grammar. (Terms like 'morphological component' and 'morphological system' will be used here for the sake of convenience and for conceptual purposes to refer to the set of elements and rules used for derivation and inflection. For fuller discussion of the controversies surrounding the

issue of whether an autonomous morphological component of the grammar exists and what its properties might be. This conception naturally excludes some of the processes to which the term 'morphologization' has been applied and that have appeared in discussions of the difference between morphologization and grammaticalization. An example is Modern German *heute* 'today,' originally a hypostasis of an early Old High German phrase reconstructed as **hiu tagu* 'on this day.' Joseph (2003) claims that such hypostases are much better characterized as morphologization than grammaticalization: although a once transparent phrase has been reduced to an adverb whose morphological structure is synchronically opaque, the end result *heute* is, in his view, "as grammatical (or not, as the case may be) before the phrase was reduced as it is afterwards," (Joseph, 2003: 477) and so the term 'grammaticalization' does not apply. In the view suggested here, neither 'grammaticalization' nor 'morphologization' is a good label for the history of *heute*. The change **hiu tagu* > *heute* is little different from the histories of words like *stirrup* or *sheriff*, once also transparent compounds (Old English *stīgrāp* 'mounting-rope,' *scīr-gerēfa* 'shire-reeve') that have been rendered opaque through a combination of sound and semantic change. If precision in terminology is to be achieved, **hiu tagu* > *heute* is really a minor adjustment to the lexicon, hence a lexical change: what started out as, or soon became, an idiomatic prepositional phrase functioning adverbially (a polymorphemic adverb, so to speak) underwent univerbation and phonological reduction – probably in that order – and came out as a monomorphemic adverb. When exactly it became morphologically opaque is difficult to say (this is a famous chicken-and-egg question in historical morphology), although it is clear that the semantic specialization or idiomatization was a precondition for it. There was no change to the morphological rules or building-blocks of the language, and hence no morphologization in any meaningful sense.

This is not to suggest that no phrasal contractions qualify as morphologizations, but it depends somewhat on individual conceptions of the morphology of a grammar, which, as alluded to above, vary widely and wildly from framework to framework. Hypostases of the *heute*-type (further examples include Eng. *to-day, to-night,* Lat. *īlicō* 'right away' < **in stlocō(d)* 'on the spot,' Russ. *voobšče* 'in general' < *vŭ obšče*) probably do not qualify under most current conceptions of the morphology (though some earlier ones subsumed the whole lexicon within it, meaning that any change to the lexicon would be simultaneously a morphological change). But less clear are crosslinguistically common developments like Span. *vuestra merced* 'your grace' becoming reanalyzed as the formal 2nd person pronoun *usted*: this is a morphologization if one takes pronouns to be part of the morphological system (as, for example, in their capacity to provide phonologically overt expressions of features manipulated by the syntax), or merely a lexicalization under other frameworks (with, to be sure, morphological ramifications, such as the spread of originally 3rd-singular verb forms like *habla* 'speaks' that were used in agreement with *vuestra merced* into the 2nd-singular paradigm slot alongside *hablas*).

Morphologization of a Phonological Rule

The most familiar type of morphologization is the reanalysis of a phonological rule as a morphological one. The identification of this as a type of linguistic change goes back to Kruszewski (1881), who, among the examples he discusses, mentions the use of umlaut to mark plurals in German; this has subsequently become the most famous example of the type. Umlaut was a sound change that affected West and North Germanic languages during the first millennium A.D., apparently beginning in the north and spreading southward. There were several different umlauts; the one that concerns us here is *i*-umlaut, which was the fronting of a back vowel (or diphthong beginning with a back vowel) before a syllable containing either *i* or the palatal glide *j*. As long as this trigger was present, umlaut was simply a low-level phonetic process; over time, however, the *i*'s and *j*'s that had caused umlaut either weakened or disappeared, and what had been simply a predictable phonetic alternation was phonologized.

One important class of umlauted forms were the plurals of nouns whose plural suffix had contained *-i-*, such as Old High German *gast* 'guest' pl. *gesti*, *apfel* 'apple' pl. *epfili* (Modern *Gast Gäste*, *Apfel Äpfel*). At some point the umlaut of the vowels associated with these plurals became reanalyzed as a plural marker itself, and spread to many words where originally no umlaut had taken place because the phonological conditions for it had not been met. Thus, the Old High German *o*-stem plurals *scazza* 'jewels,' *halsa* 'necks,' and *suarma* 'swarms' became Modern German *Schätze, Hälse, Schwärme*, the plurals of *Schatz, Hals, Schwarm*.

The individual steps in this process have been much discussed. It has been frequently averred, most recently in Janda (2003: 409ff.), that the phonemicization of umlauted vowels preceded the loss of the conditioning environment, the reasoning being that if umlaut were simply conditioned by *i* or *j*, the loss of those entities would have automatically caused the simultaneous disappearance of umlaut. This is not

the place to entertain this issue in any detail, but a few observations may be offered. Umlaut prior to the loss of *i* and *j* was surely comparable phenomenologically to the lengthening of vowels in Modern English before voiced consonants. It is a universal fact, due to vocal-tract physiology, that vowels are lengthened somewhat before voiced consonants; but in English, the lengthening is considerably greater than can be accounted for on the basis of physiology alone. The extra lengthening must be due to a rule of English phonology that lengthens vowels before voiced consonants above and beyond any physiologically automatic lengthening. (Apparently, some learners interpreted the automatic lengthening as due to a lengthening rule and incorporated such a rule into their grammars; the result was greater-than-original lengthening in their output and in the output of subsequent generations.) Similarly, the fronting of back vowels by umlaut, at first purely physiological in nature (due to anticipation by the articulators of the high front vocoid), must have (through similar reanalyses on the part of learners) grown to exceed whatever automatic fronting was induced by the following high front vocoid. That does not mean that the front vowels were phonemic; as long as their environments were predictable, all that needed to be learned was an automatic fronting rule in a certain environment. It only became phonemic when a learner missed the rule, and deduced that the fronted vowels were morphological or lexical. This either happened because the learner heard the *i*'s and *j*'s but did not pay proper attention to them, or because the learner missed the *i*'s and *j*'s.

In an important monograph, Klausenburger (1979), resuscitating and adapting Kruszewski's original framework, sought to situate our understanding of morphologization within an explicit theory about morphophonemic rules. Noting that allomorphs are best defined as phonologically different variants of a morpheme rather than simply phonetically different ones (i.e., allomorphs differ from each other by virtue of having different phonemes, not different allophones), he located morphologization already at the time that a phonetic difference was phonologized and produced different allomorphs. To take a concrete example, /s/ in early Latin developed an intervocalic allomorph [z] which was subsequently rhotacized to [r]; this was classified as a different (and already existing) phoneme, /r/. A morpheme like *ges-* 'wage, carry' appeared in two phonetically predictable forms, [ges] and (before vowel) [gez], the second of which later became rhotacized to [ger]. Since the distribution of [r] (unlike [z]) was not predictable ([r] occurred in all word positions), what had been a form phonetically predictable on the basis of its allophones was now predictable only on the basis of its morphological distribution (that is, in those morphological categories in which the morpheme was followed by a vowel–initial suffix). This, for Klausenburger, represents the true 'morphologization' (or, as he puts it, technically 'semi-morphologization') of an original phonetic, now phonological, distinction. Thus any subsequent changes, such as the reanalysis of the *r* (or the *s*) as signaling some specific piece of morphological information, would be merely a solidification of an already present morphological conditioning factor.

An important precondition for morphologization, either under Klausenburger's localization of it or under more traditional views that localize it slightly later in the process, is that the original source of the alternation (phonological rule in these cases) be rendered inaccessible to the learner, forcing the learner to ascribe the alternation to something else. Once [gez] turned to [ger] in the Latin example above, there was no evidence in the primary linguistic data available to a learner that the alternation was motivated by phonological principles. Similarly, in Modern English, verbs can sometimes be formed from nouns ending in voiceless fricatives simply by voicing the fricatives: *shelf/shelve*, *mouth* [θ]/*mouth* [ð], and so forth. The alternation was originally purely phonologically conditioned, as any voiceless fricative between two voiced segments was automatically voiced; in the nouns, the fricative was usually word-final, whereas in the verb, it preceded verbal derivational and inflectional suffixes that have since been lost. As that old verbal morphology disappeared, and as borrowings from French with word-initial [v] resulted in a phonemic contrast between [f] and [v], the original phonological motivation for the voicing was obliterated, leading to its reinterpretation as morphologically motivated. In truth, more can be made of this than is perhaps necessary, since a precondition of all reanalysis is presumably the opacity (or, at the very least, ambiguity) of the motivation for some feature in the data.

Morphologization of a phonological alternation is stated by Anderson (1988: 336) to change only the formal expression of a category rather than the set of morphological categories in the grammar. Under his view, a change to the morphological system must entail change to the set of morphological categories rather than simply their expression. In the present treatment, however, the morphological system is not defined so narrowly, and a change to the morphological system also includes changes to its rules (rules that "specify [the] structural changes that determine the formal reflections of morphological categories," Anderson, 1988: 334). German umlaut, as all agree,

is a morphological rule; thus, it follows that morphologization of a phonological rule entails change to the morphological system, and is more far-reaching than, for example, just replacement of one morpheme by another.

Opacity of the function or role of a segment was mentioned above as a necessary precondition of the morphologization of a phonological rule; it is also a precondition of a second type of morphologization, not normally treated separately, namely the morphological reanalysis of a segment or sequence (rather than of an alternation) by metanalysis of a root, stem, or other affix. An example is the French agent-noun suffix *-ier* being renewed as *-tier* when added to words ending in a vowel, such as *bijou-tier, chapeau-tier, indigo-tier*; the *-t-* was abstracted from forms like *égout-ier, charpent-ier*, where it was part of the stem. (Several other vowel–initial suffixes underwent the same change, though historically there has been some fluctuation in how widely the *t*-initial variants have spread; for details, see Nyrop, 1936: 57–61). Suffixes frequently 'grow' diachronically in this matter; a familiar example is the growth of the Latin suffix of appurtenance *-nus* to *-ānus* and further to *-iānus*: the first is seen, e.g., in *Rōmā-nus* 'Roman,' which was metanalyzed as *Rōm-ānus* to create, e.g., *Tulli-ānus* (to *Tullius*, name of a Roman gens), itself metanalyzed as *Tull-iānus* to form adjectives like *Cicerōn-iānus*. Such processes occur frequently in artificial written language as well, especially in chemistry and zoological nomenclature, as in the abstraction of a suffix *-cosa* to form genera of wolf-spiders from the name of the type genus *Lycosa* Latreille (really *Lyc-osa* < Gk. *luk-õsa* 'tearing like a wolf') such as *Schizo-cosa* Chamberlin ('split' [*schizo-*], from the excised tips of the transverse arms of the median septum of the epigynum in the female) and *Musteli-cosa* Roewer (Lat. *mūstēla* 'badger'; H. D. Cameron, p. c.).

Such morphologization also causes new inflectional morphology to arise. In the Jersiais dialect of French, historically final *-r* disappeared, while *-rC* became *-r*, as in [me] 'sea' (< OFr. *mer*) but [kɔr] 'body' (OFr. *cors*). Nouns and adjectives ending in *-r* therefore lost the *-r* in the singular but retained it before the (subsequently lost) plural marker *-s*: [ave] 'child' (< OFr. *aver*, lit. 'a belonging,' cp. Standard French *avoir*), pl. [avɛr]; [dü] 'hard,' pl. [dür] (< OFr. *dur*). The resulting alternation sg. *-ø* : pl. *-r* led to a reanalysis whereby *-r* was interpreted as a plural suffix, leading to its (limited) spread to some words that never ended in *-r* in the singular (Morin, 1986). In Northern French, [*-z*] has been reanalyzed as a feminine marker in adjectives, generalized from adjectives where it was a surviving stem-final consonant, e.g. [žoli] 'beautiful,' fem. [žoliz].

Not all metanalyses are morphologizations. In the reanalysis known as Watkins's law, a third-singular form of a verb has become opaque, is reanalyzed as ending in zero, and thereby becomes the base for a new paradigm. The example that led to the law's name is Watkins's analysis of the Old Irish *t*-preterite (Watkins, 1962), where he showed that the preterite marker *-t-* to which the preterite desinences are added was itself originally the 3rd-singular preterite ending. Here the inflectional ending **-t* lost its specification as an agreement marker and became reinterpreted as a tense marker. In this reanalysis, we have a resegmentation, but the *-t-* remains a morpheme throughout the change, though changing somewhat in function. Other persons of the verb can be reanalyzed in this way as well: in certain southeast Peloponnesian dialects of Modern Greek, for example, the *-n* that is historically the 1st-singular imperfect desinence (e.g., *(e)fórun* 'I wore, put on') has been reanalyzed as an imperfect suffix in certain verbs (whence singular *fórun-a -as -e* pl. *fórun-ame -ate -ane*; see Pantelidis, 2003).

The examples of morphologization of phonological alternations discussed so far involve a shift from interpreting one feature of a category as the marker of the category to interpreting another feature of the category as its marker. This is in keeping with Anderson's statement that no new category is created by the morphologization of a phonological rule.

Morphologization of Syntactic Structures

Morphologization that results from the reanalysis of independent words as derivational or inflectional affixes is often subsumed under grammaticalization, as stated earlier. Examples are legion; one will suffice to illustrate. In Karelian dialects, a postposition was reanalyzed as a case-ending, creating a new comitative case ending in *-kela*; the evidence that it no longer functions as a postposition comes from the fact that it is added not only to nouns but also to their modifiers, and participates in vowel harmony with the root (Comrie, 1980). If the independent word undergoing the shift is already a function word like a pronoun, the change may or may not be labelable as morphologization, depending on whether pronouns are considered part of the morphology or not (cf. *Introduction* section above). Thus, for example, a body of evidence suggests that in colloquial Modern French, the first and second person subject pronouns have been reinterpreted as proclitics; when disjunctive pronouns are used in addition, the clitics then function essentially as agreement prefixes (type *Moi, je pense* > *moi j-pense*, where *moi* is the innovated subject

pronoun and *j-* is an agreement marker; Fonseca-Greber and Waugh, 2003).

Anderson (1988) claims that the morphologization of independent lexemes normally creates new categories, in contrast to the morphologization of a phonological rule. Counterexamples to this claim can be found, however. It is generally agreed that the ablative singular case of thematic nouns in Proto-Indo-European, traditionally reconstructed as **-ōt*, consists of the thematic stem-vowel **-o-* plus a postposition **-(H)ot* or **-(H)at* 'from' (where H = an undetermined 'laryngeal'; *see* **Proto-Indo–European Phonology**) that still survives as an independent word in Balto-Slavic (e.g., Russian *ot* 'from'). The ending **-ōt* is therefore the result of the morphologization of an old postposition as in the Karelian comitative; yet in this case no new morphological category was created. The language already possessed an ablative case in the other nominal declensions as well as in the pronouns. (What is imperfectly understood is why exactly the postposition was captured only in this stem-class and only in the singular, but that is a separate issue.) Examples of this type of morphologization, in which a new desinence is formed by grammaticalization but no new overt morphological category comes into being, are not uncommon; a few others are known even from Proto-Indo-European, as well as elsewhere (e.g., the Sanskrit 2nd sing. imperative middle ending *-sva*, originally a reflexive pronoun that was captured as a desinence only in this place in the imperative middle paradigm).

Whether it is true that a new category is always created by the morphologization of syntax depends also on whether one subscribes to theories that posit underlying categories for languages where those categories are not overtly represented on the surface. Thus, some might well claim that Karelian always had an underlying comitative; at one stage, it was expressed by a postpositional phrase, and at a later stage it came to be expressed inflectionally. There is, of course, considerable debate over these issues, and this is not the place to try to resolve them. A second difficulty with the literature on this matter is a tendency to reify the language being studied (as just seen in the statement, 'Karelian always had a comitative'). Learners do not come to the language-learning task knowing what categories already exist in the grammar that they are trying to acquire, but only with the set of potential categories afforded by universal grammar. A category does not have to be present in a target grammar for the learner to interpret the data as reflecting the existence of that category. (The reinterpretation of motion verbs in many Southeast Asian languages as prepositions is a prime example of this.)

This is not to suggest that morphologization is unconstrained with respect to possible categorizations on the part of learners. Just how constrained it is, and what it is constrained by, are very broad issues in language acquisition that still await resolution.

The reanalysis of a syntagm as a sequence of bound morphemes led Talmy Givón to say what has become perhaps the most familiar statement in historical morphology, "Today's morphology is yesterday's syntax" (1971: 413). The claim is that morphological patterns that involve sequences of underlying parts of speech whose ordering would be exceptional synchronically as sentential constituents are the result of morphologization of earlier syntactic patterns. To take a standard example from English, compounds such as *nutcracker* have object-verb order, which is at variance with the normal order of those elements in the syntax today; this compound is said then to be evidence of object–verb order at an earlier stage of the language.

Much study has been devoted to determining the extent to which Givón's aphorism is true; the consensus is that, while suggestive, the statement is too problematic upon close examination to be a reliable principle for syntactic reconstruction. First, not all polymorphemic words originated in the grammaticalization of originally separate words, or at least not at a time-depth to be useful for historical linguistics. Thus, the 3rd plural ending *-n* of verbs in Spanish has been a 3rd plural desinence as far back as we can trace its history, over 5000 years to Proto-Indo-European **-nt(i)*; there is no evidence that this was ever anything but a 3rd plural ending. Second, while it is true that earlier stages of English (especially Old English) admitted the syntactic order object–verb more commonly than English does now, this means neither that that was the default order, nor that *nutcracker* and its ilk have anything to do with that order; verb–object was also common, and compounds of the *nutcracker*-type are found in most branches of Indo-European, regardless of the word-order in those languages. Even if *nutcracker* was a reflection of earlier verb–object order, it is unclear what that really means; we would not have a clearer understanding of the syntax of earlier English in any meaningful way. Syntax is not the same as word order; the latter is simply a byproduct of the former. The conclusion is that polymorphemic constructions must be analyzed on a case-by-case basis, and cannot be automatically interpreted as magic windows onto the past.

The mental lexicon is the stored mental representation of what we know about the words in our language. A critical question in the cognitive science and neuroscience of language is to determine the properties of these representations, especially where complex forms are concerned, and how they participate in processes of language comprehension and production. This is a relatively recent development. Earlier psychological investigation of the mental lexicon was dominated by research in English. Because of the properties of the English language, coupled with a primary focus on the recognition of visually presented simple words, relatively little attention was paid to the internal structure of lexical representations. Over the last two decades, however, with a marked broadening of the crosslinguistic spread of experimental psycholinguistic research, and growing interest in the processing implications of lexical complexity, issues of lexical representation have moved centre stage, with the role of morphology as a key element. This research has focused on three main topics – the cognitive representation of complex forms, regularity and irregularity in inflectional morphology, and crosslinguistic contrasts in morphological processes.

The Cognitive Representation of Complex Lexical Forms

Considered in the functional context of language comprehension and production, where lexical representations play a key role in mediating between form and meaning, there are two kinds of questions that need to be asked. These are, first, questions about the properties of a core "lexical entry," defined as the central mental representation of a word's syntactic, semantic, and abstract phonological properties. The issues here bear at least a family resemblance to the kinds of problems that might be raised in a linguistic context.

The mental lexicon is the stored mental representation of what we know about the words in our language. A critical question in the cognitive science and neuroscience of language is to determine the properties of these representations, especially where complex forms are concerned, and how they participate in processes of language comprehension and production. This is a relatively recent development. Earlier psychological investigation of the mental lexicon was dominated by research in English. Because of the properties of the English language, coupled with a primary focus on the recognition of visually presented simple words, relatively little attention was paid to the internal structure of lexical representations. Over the last two decades, however, with a marked broadening of the crosslinguistic spread of experimental psycholinguistic research, and growing interest in the processing implications of lexical complexity, issues of lexical representation have moved centre stage, with the role of morphology as a key element. This research has focused on three main topics – the cognitive representation of complex forms, regularity and irregularity in inflectional morphology, and crosslinguistic contrasts in morphological processes.

The Cognitive Representation of Complex Lexical Forms

Considered in the functional context of language comprehension and production, where lexical representations play a key role in mediating between form and meaning, there are two kinds of questions that need to be asked. These are, first, questions about the properties of a core "lexical entry," defined as the central mental representation of a word's syntactic, semantic, and abstract phonological properties. The issues here bear at least a family resemblance to the kinds of problems that might be raised in a linguistic context.

In addition, however, there are important questions to be asked about perpetual "access representations" and about the processes which operate upon these. What are the mechanisms whereby the sensory input, spoken or written, is linked to a given lexical entry? Typically, this process is thought to be mediated via modality-specific representations of word forms, which provide the perceptual target for the early stages of lexical access and word recognition.

It is still a matter of intense debate how complex lexical forms are centrally represented, and how these representations are accessed. Three principal kinds of approaches can be identified – fully decompositional accounts, assuming morphologically structured lexical representations which are accessed by decomposing complex forms into their constituent morphemes; dual route accounts, where complex forms are typically represented in decompositionally, but are accessed both as whole forms and in a decomposed format; and full listing accounts, where complex forms are stored and accessed as unanalyzed whole forms, so that morphological organization does not play an independent role in either central representation or in access to these representations.

These types of account tend to ally themselves with very different assumptions about the general computational properties of cognitive systems – whether they are based on distributed representations or on a network of interacting localist nodes. Decompositional and dual route models, which we focus on first, typically assume localist accounts, where the specific form and meaning associated with a given word – or with its decompositional components – is represented in terms of labeled symbolic nodes, and where lexical access and selection depends on excitatory and inhibitory interactions between these nodes. Behavioral data, from a range of experimental psycholinguistic tasks, is then used to make inferences about the properties of these representational nodes, and how they are organized in a processing hierarchy leading from form to meaning.

Two kinds of evidence have dominated research of this sort – experiments examining the clustering of frequency effects, and experiments using priming tasks. The frequency of occurrence of a lexical entity determines speed and accuracy of response in a timed recognition task such as lexical decision ("Is this a real word or not?"). In a hierarchically organized decompositional system, it is argued that frequency effects will collect at specific points of the system. For example, if there is a lemma level of representation, into which feed all of the inflectional variants of a given noun or verb stem, then the frequency effects for each of these variants should follow the summed (or base) frequency across the lemma, rather than being driven by the frequency of occurrence of each surface form separately.

Research along these lines has been the principal input, for example, into the dual route model developed by Baayen, Schreuder, and others, building on earlier work by Caramazza (Caramazza *et al.*, 1988; Baayen *et al.*, 1997). The first stage of this type of model consists of access representations both of words as a whole and of their potential components (so that *dogs*, *dog*, and *-s* are all separately represented), and where complex forms are recognized either through a whole word route or through a decompositional route. The specific patterning of response times to singular and plural forms, for example, as a function of their respective surface frequencies and of their summed base frequency, is then used to deduce whether plural forms are recognized by direct lookup via these whole word access representations, or whether recognition is based on decompositional parsing into morphemic components. These questions have been pursued for both inflectional and derivational morphology across a range of languages, although the story has become very intricate as the notion of frequency has itself become increasingly complex.

Priming experiments approach questions of representation and organization in a different way, by exploiting the phenomenon of repetition priming, typically in speeded recognition tasks. The underlying assumption is that if two words share a common element at some level of representation – for example, the pair *darkness* and *dark* may share the morpheme {dark} – then the activation of this element by the prime word will affect responses to a target word sharing the same element. Different versions of this basic paradigm can then be used to tap into different levels of internal representation. In crossmodal priming, the prime and target words are presented in different modalities (for example, a spoken prime and a written target), in order to tap into central lexical representations, rather than modality-specific access representations. Marslen-Wilson, Tyler, and colleagues have used this task to argue for a decompositional account of English derivational morphology (as discussed in the section 'Crosslinguistic Contrasts in Morphological Processes' below), where semantic transparency plays a major role in determining whether central lexical representations are morphologically structured or not (Marslen-Wilson *et al.*, 1994). Synchronically transparent prime/target pairs such as *punishment/punish* prime each other robustly, but no priming is found between opaque pairs such as *department/depart* or *casualty/casual*.

A different picture emerges, however, when priming tasks are used that tap into modality-specific access

representations. A case in point is masked priming, where a visual prime word (followed by a visual target) is presented so briefly that the reader is not aware that the prime is present, and simply makes a lexical decision to the target. Here we see, even for English, that there is strong priming not only between transparent pairs such as *bravely/brave*, but also between pairs such as *hardly/hard*, which are synchronically opaque, and even for pairs such as *corner/corn*, where *corner* clearly has no morphological interpretation as {corn +-er} (Rastle *et al.*, 2000). The process underlying these effects is nonetheless morphologically sensitive, since pairs such as *scandal/scan*, where {-dal} is not a derivational affix in English, do not show priming. Similar patterns are reported for French by Longtin and colleagues, where transparent pairs such as *gaufrette/gaufre* ('wafer/waffle') and pseudostem pairs such as *baguette/bague* ('small stick/ring') both prime robustly, but pairs such as *auberge/aube* ('inn/dawn') do not (Longtin *et al.*, 2003). When the prime is overt (not masked), however, then only transparent pairs prime, for both French and English. Results like this point to a distinct, modality-specific level of access representation, where all morphologically decomposable surface forms are segmented into potential stems and affixes by a process which is blind to semantic factors, and even to higher order lexical structure.

These localist models, with their decompositional leanings, contrast strongly with current full listing models, which typically assume distributed connectionist accounts of lexical representation and processing. Here the mapping from form to content is implemented as the learned pattern of connections among the elementary units in a multilayer neural network. Nowhere in the system is either the phonological form or the semantic content of the word explicitly represented, except indirectly as a pattern of connections over units. Morphological relations between words, seen as regularities in form–meaning relations, are captured as subregularities in the form-to-meaning mapping process, and are not assigned any independent status in the system. This approach to lexical representation, although it has had some impact in derivational morphology, has had its major influence in the domain of inflectional morphology, to which we now turn.

Regularity and Irregularity in Inflectional Morphology

The clash between localist and distributed approaches to lexical representation has reached its widest audience in the context of the 'words and rules' debate that has flourished in the cognitive sciences since the mid–1980s. This debate has taken English regular and irregular inflectional morphology as its principal empirical focus, as a way of addressing fundamental questions about whether rulelike behavior should be explained in terms of symbolic computation (Pinker, 1999; Pinker and Ullman, 2002), or in terms of connectionist learning systems, containing neither rules nor symbols (Rumelhart and McClelland, 1986; McClelland and Patterson, 2002). The reason why the English past tense is relevant here is because of the sharp contrast that it offers between a potentially rule-based system – the procedure for forming the regular past tense by combining a phonologically unchanged stem with an inflectional suffix (as in *jump/jumped*, *agree/agreed*, etc.) – and an idiosyncratic set of irregular forms where there is no predictable relationship between the stem and its inflected past tense form (as in *bring/brought*, *give/gave*, etc.), and no basis for segmentation of these irregular forms into a concatenative stem + affix format.

Leaving aside issues about the nature of mental computation, which are outside our current remit, this debate has raised basic questions about how morphological regularities are instantiated in a cognitive system and how this system is structured in terms of brain organization. From a no-morphology, single-system point of view, regular morphological phenomena – in this case the process of past tense formation in English – are represented internally as part of a continuous, distributed process where there are no qualitative differences in the representation of simple or complex forms. Not only is there no qualitative distinction between regular and irregular forms, but also there is no separation between different types of morphemes – for example, noun or verb stems as opposed to grammatical morphemes such as the English past tense and plural morphemes. Going along with this single-system view of cognitive organization is a similar view of the underlying neural system – that it too is organized as a single undifferentiated process.

The contrasting approach argues not only that the representational system does make qualitative distinctions between types of morphemes – and between regular and irregular past tense morphology in English – but also that these distinctions are linked to a significant differentiation in the underlying neural machinery. Evidence from neuropsychology (Marslen-Wilson and Tyler, 1998), in the form of selective deficits following injury to the brain, strongly suggests that aspects of the neural systems required to produce and comprehend regular inflectional forms are dissociable from those required for irregular forms (in English). Patients with left hemisphere damage to core language areas often show major

impairments when confronted by regular inflected forms, while their performance is relatively intact for irregular forms.

More recently, a combination of behavioral and neuro-imaging research, both with patients and with unimpaired adults, has made it possible to flesh these claims out in more detail (Tyler *et al.*, 2005). General lexical access processes seem to be mediated by temporal lobe structures, linking sensory inputs to stem-based representations of lexical form and meaning. Additional left hemisphere frontal lobe systems are brought into play, however, when regular inflected forms like *jumped* or *smiled* are encountered, with their characteristic stem + affix structure. Intact left frontal systems, as well as intact pathways connecting frontal and temporal lobes, seem to be required to support the processes of morphophonological parsing triggered by inputs such as *jumped*, where the stem morpheme {jump} enters into temporal lobe access processes but the inflectional morpheme {-d} obligatorily engages left frontal areas. Irregular past tense forms, in contrast, do not have a segmentable stem + affix structure in English, and must be stored and accessed as whole forms. This can largely be handled by temporal lobe access processes, so that performance on irregulars is relatively less impaired by left frontal damage that disrupts the regulars.

This decompositional approach to access and representation is consistent with the behavioral data reviewed in previous sections. There is evidence that complex inflectional and derivational forms are decomposed early in the access process, and that different neural processing streams may be engaged by the different types of morpheme that are involved. However, we are very much at the beginning of the process of understanding the different neural systems involved in the representation and access of complex linguistic forms. But it is likely that these are pointers to how research into human language will develop in the context of a cognitive neuroscience of language, where functional neuro-imaging makes it possible to directly visualize the brain activity associated with different aspects of language function in the morphological and other linguistic domains.

Crosslinguistic Contrasts in Morphological Processes

Both cognitive and linguistic accounts of lexical structure ultimately have to be situated in a universalist context. As other articles in this encyclopedia amply demonstrate, there is an immense variety of lexical arrangements across languages. A relatively new aspect of the cognitive enterprise is the attempt to explore and describe this crosslinguistic variation from a functional perspective. Do we find evidence for common underlying processing principles in lexical organization? The results so far suggest that lexical systems are as notable for the differences in their underlying computational properties as for their similarities.

A language like English, for example, can be described as exhibiting a range of word formation procedures, each of which have their diagnostic behavioral characteristics. Derivational and inflectional processes in English are arguably combinatorial in nature, with the same morpheme combining with other morphemes across a morphological family to create the basis both for meaning and for structure. Thus, the morpheme {dark} in *darkness* is the same lexical and cognitive entity as the {dark} in *darkly*. Similarly, the {-ness} in *darkness* is the same as the {-ness} in *toughness*, with parallel claims being made for regular inflectional processes. The diagnostic behavioral evidence for these claims comes from a specific set of experimental effects – for example, stem priming (where *darkness* primes *dark*), affix priming (where *toughness* primes *darkness*), and so forth (Marslen-Wilson *et al.*, 1994). At the same time, English also has a very productive set of compounding processes, which, in contrast, do not appear to be combinatorial in nature. For example, unlike the derivational case outlined above, shared morphemes between transparent compounds do not lead to priming unless the compounds as a whole are semantically related. Thus *headache* does not prime *headscarf*, even though they both transparently contain the morpheme {head}. This is not consistent with a morphemic, combinatorial story, where {head} is a constituent of *headache* and *headscarf* in the same way that {punish} is a constituent of both *punishment* and *punishable*. Instead, each compound seems to require a separate lexical entry, perhaps reflecting the unpredictability of a compound's meaning from the simple combination of its constituents.

These kinds of behavioral effect can be used to explore how far other languages share similar word formation systems – and therefore similar underlying processing procedures. One case study was for Polish, a Slavic language with an rich morphological system, and which, like English, employs a concatenative derivational morphology, combining stems with sequences of prefixes and affixes. Unlike English, essentially all surface forms are morphologically complex, combining a bound stem with one or more suffixes. Thus the word *przybiegłam* 'I ran up' consists of the stem *-bieg-*, the derivational-aspectual prefix *przy-*, and the inflectional suffixes *-ł* and *-am*,

indicating the past tense and the 1st person singular feminine. A series of studies, chiefly using delayed repetition priming tasks to reduce semantic effects, reveals a profile of results that is very similar overall to English (Reid and Marslen-Wilson, 2003). There is clear evidence of stem and affix priming, and the same strong effects as in English of semantic transparency in overt priming tasks that tap into central representations. The profile of results for the different kinds of priming relationship suggest that Polish and English have a great deal of common in terms of basic morphological mechanisms. Although they are very different languages in important respects, they both fit an overall template that we interpret in terms of a morphemically organized and combinatorial mental lexicon, operating in a similar computational framework.

A valuable typological contrast is provided by Semitic languages, such as Arabic and Hebrew, which possess a complex nonconcatenative morphology, where the surface phonetic form is constructed by interweaving two or more abstract morphemes – the consonantal root, carrying semantic information, and a word pattern which specifies the syntactic category and the phonological structure of the surface form. These are abstract, bound morphemes that never surface as phonetic forms on their own. Do these abstract entities function cognitively in ways comparable to stems and derivational morphemes in concatenative morphologies such as English or Polish? Using a range of behavioral techniques (including both masked and overt priming tasks), extensive research in both Hebrew and Arabic (e.g., Frost *et al.*, 1997; Boudelaa and Marslen-Wilson, 2001) finds evidence for priming between pairs that share the same consonantal root – for example, the Arabic prime word /ʔidxaalun/ ('inserting') speeds responses to the target /duxuulun/ ('entering'), where prime and target have in common the root {dxl}. Strikingly, and quite differently from English and Polish, semantic transparency does not determine priming in either masked or overt priming tasks. Across both types of task, priming is just as strong when the prime is semantically opaque, as in the form /mudaaxalatun/ ('interference'), which also shares the root {dxl} with the target /duxuulun/, but where the meaning of the form is not synchronically predictable. This preservation of overt root priming under conditions of semantic opacity shows up consistently in both Arabic and Hebrew. Analogously to affix priming, priming is also found between pairs that share the same word pattern but have different roots and different meanings – to take an Arabic example, for pairs like /xudˤuuʕun/ and /ħuduuθun/ ('submission'/'happening') which share the word pattern {fuʕuulun}.

These results for Semitic languages suggest strong support for a decompositional, combinatorial system, with abstract morphemes combining to produce the surface form, and being separated out in the process of recognition. The absence of a semantic transparency effect in overt root priming, however, signals a potentially major difference in the principles underlying the role of morphological combination in central lexical representations.

A final set of illustrative comparisons involves Mandarin Chinese. This has essentially no derivational morphology, so that compounding is its only productive means of word formation, under conditions where there is considerable communicative pressure due to rampant homophony at the syllabic level. Indeed, recent analyses suggest that around 70% of word types in Mandarin are disyllabic compounds, which raises the question of whether these are represented as whole forms (as in English), or whether a more combinatorial, morpheme-based account holds here. Mandarin seems to be a plausible environment for such an account, because of the salience of individual morphemes in the spoken language and in the writing system. Extensive research using auditory-auditory repetition priming shows that this is not the case (Zhou and Marslen-Wilson, 1995). Compounds are represented as separate lexical entries, and not as combinations of their constituent morphemes. This means that Mandarin, unlike the other languages we have studied, does not have a system of word formation that is decompositional and combinatorial.

Even within this small sample of languages, we see a wide range of underlying processing procedures brought into play to support lexical representation and processing. Mandarin Chinese seems to lie at one extreme, with apparently no combinatorial procedures for word formation, and with a lexicon made up of whole forms, where the behavioral evidence suggests that compounds and the words that make up these compounds all have separate lexical representations. English has a similar system for compounding, but also has a decompositional system of word formation and representation, reflecting the different processing requirements of derivational procedures that operate on a combinatorial basis, and that deliver predictable and compositional meanings. In this respect English parallels the broad characteristics of a language such as Polish, which has a much richer and more complex morphological system. Both of these languages share with Arabic (and Hebrew) a combinatorial and decompositional approach to lexical representation. In these Semitic languages, however, morphological representation appears to play a more fundamental structural role, so that no surface form can be produced without some

underlying process of morphophonological combination. This delivers both the surface form, and its basic syntactic and semantic properties.

These differences in lexical representation, although reflecting only a preliminary sample of languages, and reflecting a single type of experimental approach, nonetheless suggest that unitary models of the representation and processing of complex lexical forms may not be possible across languages. Although all lexical systems must share the same underlying cognitive and neural constraints on representation, process, and acquisition, these constraints seem to be sufficiently broad to allow different systems to be constructed on apparently quite different organizational principles.

Morphology in Parallel Distributed Processing

M S Seidenberg, University of Wisconsin, Madison, WI, USA

© 2006 Elsevier Ltd. All rights reserved.

Parallel distributed processing (PDP) is a computational framework for understanding behavior and its brain bases. The approach emphasizes how behavior emerges from the aggregate activity of large numbers of simple neuronlike processing units. The behavior of the system changes over time as it learns from experience, subject to constraints imposed by the architecture of the system. PDP models are the most widely studied type of connectionist network; for brevity the terms PDP and connectionist will be used interchangeably. Such systems have been widely used

in cognitive science, but their relevance to language has been strongly questioned, largely on the basis of attempts to apply them to morphological phenomena. In 1986 Rumelhart and McClelland described a PDP model of the formation of the past tense in English. They claimed to have demonstrated that language involves the use of PDP networks rather than grammatical rules, and that linguistic phenomena are governed by general rather than domain-specific principles.

Pinker and Prince (1988) contested these claims, identifying many ways in which the model's behavior differed from people's. For example, the model did not generalize well; it was unable to distinguish homophones such as STEEL and STEAL, which have different past tenses (STEELED, STOLE); it exhibited the U-shaped learning curve typical of language learners only because the model's training protocol was engineered to produce it; and so on. Pinker and Prince proposed an alternative, dual-mechanism theory consisting of a past tense rule and a separate lexical system to handle irregular past tenses. Connectionist models, they argued, could be helpful in understanding how these mechanisms are implemented in the brain, but the important linguistic generalizations were to be found at the level of "words and rules" (Pinker, 1999).

Many linguists have found these arguments compelling and consistent with arguments against earlier learning-theoretic approaches to language (Chomsky, 1959). Pinker and his colleagues subsequently amassed a large body of empirical evidence, related to many aspects of the past tense (e.g., acquisition, skilled performance, breakdown following brain injury), that provided additional evidence for his theory (see Pinker, 1999, for summary).

For many connectionists, the Pinker and Prince arguments were less decisive, as they seemed to be about details of the Rumelhart and McClelland model rather than the principles of the connectionist approach. A model is an instantiation of critical components of a theory; limitations on the scope of the implementation guarantee that its behavior will deviate from people's at some level of detail. Whether such deviations are theoretically relevant requires additional research, which Pinker and Prince's critique stimulated.

The PDP Approach to Morphology

According to connectionist theories, the past tense in English, like other aspects of language, is quasi-regular rather than rule-governed (Seidenberg and McClelland, 1989): it is systematic but admits many exceptions, which often share structure with the 'rule-governed' forms. For example, many irregular past tenses end with the correct inflection but have an 'incorrect' vowel (e.g., SLEPT, FOUND); a high percentage of the no-change past tenses such as HIT also end with either /t/ or /d/; most irregular past tenses retain the onset and coda of the present tense, as in the rule-governed forms. These facts are not captured by theories in which the two types of forms are allocated to separate subsystems. Thus, the central claim is that there is no categorical boundary between rule-governed forms and exceptions; they are governed by the same principles, which are general rather than specific to the past tense or to language. And (it is argued), when examined closely the empirical phenomena do not exhibit the strong dissociations between rule-governed forms and exceptions predicted by the dual-mechanism theory.

This approach is different from but also complementary to traditional grammatical theorizing. Connectionist networks are not attempts to rationalize a body of well-formedness data; rather the goal is a mechanistic theory that explains how morphological, linguistic, and other types of knowledge are acquired, used, and represented in the brain. Grammatical theories are seen as abstractions about the behavior of the networks that determine performance, useful for many purposes. The network is not an 'implementation' of any grammatical theory insofar as it behaves in ways not deducible from it.

Modeling Issues

The Pinker and Prince critique launched a large number of attempts to address limitations of the Rumelhart and McClelland model. The model's limited capacity to generalize was related to the coarse way in which phonological information was represented. This representation contributed to errors on novel forms, which require recombining elements of known forms. Improving the phonological representation improves generalization and greatly reduces the number of implausible errors (Joanisse and Seidenberg, 1999; Harm and Seidenberg, 2004).

Similarly, the homophone problem was also easily remedied. Rumelhart and McClelland's model focused on the classic WUG test in which a child hears a nonsense word and produces an inflected form (e.g., plural or past tense). Thus, the model instantiated a mapping from the phonology of the present tense to the phonology of the past tense. Such systems represent homophones identically and therefore cannot learn to produce different past tenses for items such as /sti:l/. Pinker and Prince noted that adding semantic representations to the network would not fix the problem because it does not reliably indicate the

correct inflection; their examples were STRIKE, SLAP, and HIT, which are semantically similar but form the past tense three different ways. Hence, they concluded that PDP networks could not in principle accommodate homophones. However, they overlooked the solution of using both semantics and phonology simultaneously. Joanisse and Seidenberg (1999) implemented such a model. The model encoded phonological regularities that supported generalizations such as WUG-WUGGED; the model learned to use semantics in producing correct irregular past tenses, particularly lower frequency ones, and disambiguating homophones.

Joanisse and Seidenberg's (1999) model exhibits several important features. The model was not purpose-built to produce the past tense; rather, it learned about the sounds and spellings of words and how to perform various tasks: comprehension, mapping from sound to meaning; production, mapping from meaning to sound; transformation, mapping from present tense to past; and others. The well-formedness of the model's output is a function of the degree to which it satisfies semantic and phonological constraints, encoded by the weights on connections between units. The model is not tabula rasa; it is configured with the capacity to encode semantic and phonological information and to learn from experience. This type of model is now the focus of the debate (Pinker and Ullman, 2002).

Empirical Issues

The debate about connectionist models has led to a re-examination of the primary behavioral data thought to favor the dual-mechanism theory. The literature is too extensive to review here, but consider the following examples, which are representative.

Compounding

Kiparsky (1982) observed that rule-governed plurals are dispreferred as modifiers in compounds. Thus, an eater of rats is a RAT-EATER, not a *RATS-EATER. The irregular plural does not seem to be proscribed, however: MICE-EATER is acceptable. These facts seem to support the dual mechanism theory (Pinker, 1994): singular forms such as RAT and irregular forms such as MICE are represented in the lexicon; RATS is generated by rule. RATS-EATER is blocked because the rule governing the formation of inflected words applies after the rule for compounding. Gordon (1985) showed that young children also exhibit this preference pattern.

A great deal has been argued on the basis of examples such as *RATS-EATER and MICE-EATER, but what are the facts? Haskell *et al.* (2003) found that native speakers strongly prefer forms such as RAT-EATER and disprefer forms such as RATS-EATER, but rate MICE-EATER as intermediate in acceptability. Corpus analyses indicated that there is a general dispreference in the language for plural modifiers; both types occur less often than would be expected based on the frequencies of the corresponding singular forms. Haskell *et al.* (2003) proposed that the well-formedness of compounds is a graded function of probabilistic constraints, as in connectionist networks. The two primary constraints are preferences for modifiers that are singular in sound and in meaning. This explains the ordering of the preference data described above; MICE-EATER is intermediate because it satisfies the phonological constraint (it does not sound like a standard plural) but it violates the semantic constraint. Haskell *et al.* extended this analysis to compounds including other forms such as *pluralia tanta*. They also proposed an account of the origin of the constraints (that they are inherited from other forms of modification, principally adjectival phrases) and suggested how they could be acquired based on information available to the child.

Generalization

A strong claim of the dual-mechanism theory is that rule application is blind to phonological and semantic properties of words. An inflectional rule (e.g., past tense, plural) is a default that applies unless it is blocked because the relevant form is an exception stored in lexical memory. However, this generalization is easily violated. Children produce novel past tenses like SPLANG, under the phonological influence of irregular past tenses such as RANG (Bybee and Slobin, 1982). Ramscar (2002) showed that semantic factors influence generalization: in the context of drinking events, adults preferred FRANK as the past tense of FRINK, whereas in other contexts they preferred FRINKED. Thus, generalization is penetrated by information to which the rule component does not have access according to the dual-mechanism theory.

Current Status of the Debate

Although it may be hard to believe that any aspect of the English past tense has not been thoroughly dissected by now, the debate has in fact shifted in a new direction recently: to the brain. Patterson and her colleagues have studied individuals with a form of degenerative neuropathology called semantic dementia (Patterson *et al.*, 2001) in which lexical semantic information progressively deteriorates. These researchers have also studied patients with anterior

(Broca-type) aphasia, for whom semantics is intact but phonology is impaired (Bird *et al.*, 2001). The empirical question, then, is how these different conditions affect knowledge of the past tense. The striking result is that semantic dementia patients first begin to make errors on lower frequency irregular past tenses – the items for which semantic input was necessary in the Joanisse and Seidenberg (1999) model. As the disease progresses, higher frequency irregular past tenses and then eventually rule-governed past tenses are affected. In contrast, the anterior aphasics show greater impairments in generalization than in producing irregular past tenses.

Modeling research is also continuing. One goal is developing models of English embodying the same principles as Joanisse and Seidenberg (1999) but with broader coverage of the phenomena. A second is applying the same principles to more complex inflectional systems. Mirkovič *et al.* (in press), for example, developed a model of Serbo–Croatian that has inflections for number, case, and gender. This inflectional system is difficult to merely describe in rules, given the apparent exceptions and multiple contingencies that appear at every turn. However, it can be instantiated by a connectionist network that learns through exposure to a large number of examples. Plaut and Gonnerman (2000) developed a model of some aspects of infixing in Hebrew utilizing connectionist principles. Although preliminary, this research extends the modeling of inflectional morphology well beyond the overworked English past tense.

Finally, can the same principles be extended to noninflectional morphological phenomena? Seidenberg and Gonnerman (2000) offered some suggesztive observations. They argued that morphological structure emerges from correlations between form (phonology, orthography) and meaning, and that these correlations vary in degree. Morphemes are construed as underlying representations that develop in connectionist networks employing interlevel 'hidden' units. Thus they are graded rather than discrete. This approach seems well suited to classic phenomena (Aronoff, 1976) concerning forms that behave as though they are morphemes but are semantically weak (e.g., MIT in PERMIT, SUBMIT, etc.). Other aspects of derivational morphology also seem compatible with this approach, e.g., the different degrees of semantic transparency and compositionality in formally similar words such as TALKER (high), CORNER (low), and SLIPPER (intermediate). Dealing with this broader range of phenomena, in multiple languages, in an implemented computational system that adequately represents semantic and phonological information is a daunting task, one to send a person tearing back to the English past tense. Still, the relevance of PDP principles to these phenomena seems clear and worthy of further attention.

The past tense debate has struck many linguists as turgid because the English past tense has little of the complexity that inflectional systems can exhibit. However, if PDP-connectionist systems cannot handle even this minor aspect of morphological structure, it would place severe limitations on their relevance to language. It appears that the reports of the inadequacy of this approach were greatly exaggerated, at least regarding the past tense. It remains to be determined whether it can account for the much broader range of morphological and linguistic phenomena that lay beyond.

Morphology in Pidgins and Creoles

I Plag, Universität Siegen, Siegen, Germany

© 2006 Elsevier Ltd. All rights reserved.

Introduction

It is often believed that pidgins and creoles have no or very little morphology. Seuren and Wekker, for example (1986: 66), claimed that "morphology [is] essentially alien to creole languages," and in Thomason (2001), a textbook on contact languages, one can read that "[m]ost pidgins and creoles either lack morphology entirely or have very limited morphological resources compared with those of the lexifier and other input languages" (Thomason, 2001: 168; see Degraff, 2001 for more discussion and more pertinent references). Furthermore, it has been claimed that, if there is morphology in pidgins and creoles, it is (for the most part) regular, semantically transparent, iconic, or otherwise unmarked (e.g., Seuren and Wekker, 1986; McWhorter, 1998, 2000; see also Thomason, 2001: 168).

Most recently, there is a growing body of literature on pidgin and creole morphology in which these traditional views are seriously challenged (see, for example, the papers in Plag, 2003a, 2003b, and Kouwenberg, 2003). In the following, we address the traditional claims in more detail and see whether they are borne out by the facts. It will become clear that all of these claims are problematic and need to be abandoned or substantially revised. Overall, we can say that, even though pidgins and creoles seem to have less morphology than their lexifiers, there is indeed morphology in pidgins and creoles, with important differences between individual languages and also between languages of different status (pidgin or creole).

Apart from the questions about the presence and nature of morphology in pidgins and creoles discussed under 'Is There Morphology?' and 'What Kind of Morphology Is There?', the other major issue in pidgin and creole morphology is the question of how morphology arises and develops in pidginization and creolization. What is the role of the languages involved in the particular contact situation and what is the role of universal factors such as markedness and iconicity in the emergence of the pidgin and creole morphological systems? These questions are dealt with in the final section.

Is There Morphology?

Let us first turn to the question of how much morphology we find in pidgins and creoles. To answer that question, it seems necessary to distinguish between pidgins and creoles. It is often assumed that pidgins are morphologically more impoverished than creoles (e.g., Siegel, 2004a on restricted pidgins). However, typological research by Bakker (2003a) has shown that this is probably not the case. Based on a large sample of varieties, Bakker found that pidgins tend to have more, rather than less, inflectional morphology than creole languages. With regard to lexical morphology, Mühlhäusler (1997), for example, argued that rudimentary pidgins rely on syntactic means to expand their lexicon (cf. e.g., *gras belong fes* 'beard' in early Tok Pisin), whereas expanded pidgins develop morphological means as well.

A serious review of the literature on creoles also refutes the claim that there is little or no morphology in these languages. Many creoles have inflectional morphology in their nominal, verbal, or adjectival systems. Pertinent cases from numerous creoles can be found in the overviews by Holm (1988), Stolz (1989), Bakker (2003a), and Baptista (2003). Prominent examples are suffixes encoding plural and/or definiteness on nouns in Kabuverdianu (Cape Verdian Creole) or Palenquero (Baptista, 2003), the long and the short verb forms in some French-based varieties

Morphology in Pidgins and Creoles

I Plag, Universität Siegen, Siegen, Germany

© 2006 Elsevier Ltd. All rights reserved.

Introduction

It is often believed that pidgins and creoles have no or very little morphology. Seuren and Wekker, for example (1986: 66), claimed that "morphology [is] essentially alien to creole languages," and in Thomason (2001), a textbook on contact languages, one can read that "[m]ost pidgins and creoles either lack morphology entirely or have very limited morphological resources compared with those of the lexifier and other input languages" (Thomason, 2001: 168; see Degraff, 2001 for more discussion and more pertinent references). Furthermore, it has been claimed that, if there is morphology in pidgins and creoles, it is (for the most part) regular, semantically transparent, iconic, or otherwise unmarked (e.g., Seuren and Wekker, 1986; McWhorter, 1998, 2000; see also Thomason, 2001: 168).

Most recently, there is a growing body of literature on pidgin and creole morphology in which these traditional views are seriously challenged (see, for example, the papers in Plag, 2003a, 2003b, and Kouwenberg, 2003). In the following, we address the traditional claims in more detail and see whether they are borne out by the facts. It will become clear that all of these claims are problematic and need to be abandoned or substantially revised. Overall, we can say that, even though pidgins and creoles seem to have less morphology than their lexifiers, there is indeed morphology in pidgins and creoles, with important differences between individual languages and also between languages of different status (pidgin or creole).

Apart from the questions about the presence and nature of morphology in pidgins and creoles discussed under 'Is There Morphology?' and 'What Kind of Morphology Is There?', the other major issue in pidgin and creole morphology is the question of how morphology arises and develops in pidginization and creolization. What is the role of the languages involved in the particular contact situation and what is the role of universal factors such as markedness and iconicity in the emergence of the pidgin and creole morphological systems? These questions are dealt with in the final section.

Is There Morphology?

Let us first turn to the question of how much morphology we find in pidgins and creoles. To answer that question, it seems necessary to distinguish between pidgins and creoles. It is often assumed that pidgins are morphologically more impoverished than creoles (e.g., Siegel, 2004a on restricted pidgins). However, typological research by Bakker (2003a) has shown that this is probably not the case. Based on a large sample of varieties, Bakker found that pidgins tend to have more, rather than less, inflectional morphology than creole languages. With regard to lexical morphology, Mühlhäusler (1997), for example, argued that rudimentary pidgins rely on syntactic means to expand their lexicon (cf. e.g., *gras belong fes* 'beard' in early Tok Pisin), whereas expanded pidgins develop morphological means as well.

A serious review of the literature on creoles also refutes the claim that there is little or no morphology in these languages. Many creoles have inflectional morphology in their nominal, verbal, or adjectival systems. Pertinent cases from numerous creoles can be found in the overviews by Holm (1988), Stolz (1989), Bakker (2003a), and Baptista (2003). Prominent examples are suffixes encoding plural and/or definiteness on nouns in Kabuverdianu (Cape Verdian Creole) or Palenquero (Baptista, 2003), the long and the short verb forms in some French-based varieties

to mark tense distinctions or argument/adjunct status of the following NP (e.g., Veenstra (2003) with further references), the transitivity marker *-im/-em* (derived from English third-singular and third-plural pronouns *him/'em*) in Tok Pisin and other Pacific varieties, and the superlative suffix *-st* in Negerhollands (Stolz, 1989).

With regard to lexical morphology, creoles exhibit conversion, affixation, reduplication, and compounding as very common processes. These processes encode semantic categories that we also find in non-creole languages, such as agent, instrument, nomina actionis, intensification, diminutive, causative, resultative, and relational adjective. Overviews of the word-formation processes of specific creoles can, for example, be found in Dijkhoff (1993) for Spanish/Portuguese-based Papiamentu, in Degraff (2001) and Lefebvre (2003) for French-based Haitian Creole, in Braun and Plag (2003) for English-based Sranan, and in Steinkrüger (2003) for Spanish-based Chavacano (Chabacano).

In summary, it is now an established fact that creoles do have morphology, at least to a non-negligible extent. This allows us to turn in more detail to an analysis of the particular characteristics of creole morphology.

What Kind of Morphology Is There?

Given that there is morphology in creoles, two problems emerge. What is the nature of these systems and how do they come about? In this section, we shed light on the first problem. We answer the questions 'What kinds of morphology can be found in pidgins and creoles?' and 'Is pidgin and creole morphology in some sense particularly restricted?'

The first thing that is characteristic of pidgin and creole morphology in general is that it seems to be less rich than that of the lexifier languages, both in terms of formal means and in terms of the functional and semantic categories to be expressed. For example, whereas English has dozens of derivational affixes plus a small number of inflectional categories, English-based creoles generally feature by far fewer affixes (see Braun and Plag, 2003 for Sranan). Haitian Creole has a number of derivational affixes, but the inventory is again much smaller than that of French (Lefebvre, 2003). Note, however, that the inventory of derivational affixes in a creole language is not necessarily limited to a subset of the affixes of the lexifier. Creole languages also exhibit a number of innovations (see below for examples and discussion of the developmental issues involved). But even including the innovations, the total inventory of processes is still smaller than that of the lexifier.

Another type of restriction concerns the kind of processes that we find. In his survey of pidgin morphology, Bakker (2003b) observed that reduplication seemed to be conspicuously absent in the overwhelming majority of pidgins, whereas it was almost universally present in creoles. In contrast, word-class marking morphology was attested only in pidgins, and not in creoles (Bakker, 2003a). The reasons for these findings are largely unclear, but seem to have their origin in the fact that attested pidgins emerged in contact with a much wider range of lexifier languages than creoles, involving more morphologically rich languages (see Bakker, 2003a for more discussion).

Third, the nature of possible form-meaning relationships in creoles is often invoked as an important characteristic of pidgin and creole morphology, such that these languages may generally be characterized by transparent, iconic relationships in their morphological system. As we will shortly see, this is not the case either.

Transparency can be defined as the possibility of inferring a meaning of complex words from the parts of such a word. This means that the complex words must be segmentable into different morphs and that these morphs must be semantically interpretable (cf. e.g., Ronneberger-Sibold, 2001: 98). The belief that there is no semantic opacity in pidgin and creole morphology is fed by the idea that creoles are fairly young languages, so that long-term semantic drift, taken as one of the major factors leading to opacity, has had no chance to apply. McWhorter (1998: 798), for example, wrote that the "semantic irregularity of derivation arises from the inevitable process of semantic drift and metaphorical inference." However, apart from long-term semantic drift, opacity can also arise through various other mechanisms, with borrowing chiefly among them. Plag (2001) and Braun and Plag (2003) therefore argued that opacity is predicted to arise in a language emerging through language contact, such as a creole. In their study of early Sranan complex words, they showed that semantically opaque forms occur frequently even at an early stage of creole development and that the semantic transparency and regularity hypothesis cannot be upheld.

A similar picture emerges with regard to iconicity. Iconicity is a semiotic principle according to which there is a resemblance or analogy between the signifier and the signified. Complexity of meaning should be reflected in complexity of form (e.g., Mayerthaler, 1980). Conversion, for example is non-iconic in the sense that there are two meaning components with only one surface exponent. Plural marking by way of an additional morpheme is iconic because more of form signifies more of content. Reduplication to

express plurality with nouns, or repeated action with verbs, is considered iconic because more of the same form expresses more of the same content (e.g., Sapir, 1921: 79; Botha, 1988: 3). Applying the concept of iconicity to pidgins and creoles yields, however, sobering results. The fact that conversion is one of the most widely employed strategies in pidgins and creoles for deriving new lexemes indicates that iconicity does not play a dominant role in pidgin and creole morphology. With regard to reduplication, we indeed find cases of iconic reduplication, as in *mango-mango* 'many mangoes'. However, Kouwenberg and La Charité (2003) showed that there is also an abundance of productive non-iconic reduplication processes in various creoles. For example, in Ndjuká, reduplication of verbs expresses a stative result (e.g., *bai* 'buy', *bai-bai* 'bought') and in French-based creoles reduplication of adjectives expresses similarity or a diminutive (e.g., *blanch* 'white', *blanch-blanch* 'whitish').

A final characteristic of pidgin and creole morphology has often been claimed to lie in the formal means of expressing concepts. Thus, under the hypotheses of transparency and iconicity mentioned above, one would expect the avoidance of the more marked or less natural morphological encoding strategies such as ablaut, subtractive morphology, root-and-pattern morphology, tonal morphology, or those involving allomorphy. This is, however, not the case. In general, comparatively unmarked strategies such as affixation, conversion, reduplication, and compounding are the predominant processes, but instances of allomorphy are also not uncommon (e.g., in the pronoun systems of creoles), and even tonal morphology is found (Good, 2003; James, 2003). It thus seems that there is in principle no greater limit to the formal power of the morphological system of pidgins and creoles than to that of other languages.

How Does Pidgin and Creole Morphology Emerge?

There are three major sources of morphology in pidgins and creoles. Morphological markers can be taken directly from one of the languages involved in the contact ('borrowing') or they can have developed through grammaticalization. A third possibility is that the markers can be innovated by taking the phonetic/phonological form of a morpheme from one of the input languages (usually the superstrate) and using it in the function (or with the meaning) of a semantically related morphological marker from another input language (usually the substrate). The latter process has been referred to as 'relexification' (e.g., Lefebvre, 1998).

Examples of borrowing are the Spanish suffix-*ndo* in Papiamentu (Dijkhoff, 1993), the plural prefix *ma*-in Palenquero borrowed from Kikongo (Parkvall, 2000: 100), or the past tense marker *-ato* in the Italian-based pidgin lingua franca of the Mediterranean. Note that the form and meaning of the borrowed item are not necessarily totally identical to those of the donor language, which makes borrowing sometimes hard to distinguish from grammaticalization or relexification.

Instances of grammaticalized affixes can be found among preverbal markers, which in many creoles behave like bound morphemes or clitics. For example, in French creoles, *été*, *va*, and *après* grammaticalized to a tense marker *te*, a mood marker *va*, and an aspect marker *ap*. Similarly, the English object pronouns *him/'em* became a transitivity marker *-em/-im* in Pacific pidgins and creoles. It should be noted, however, that many apparent instances of grammaticalization turn out to be cases of substrate transfer or relexification on closer inspection (e.g., Plag, 2002; Siegel, 2004b).

A clear example of relexification is the case markers in Indo-Portuguese (Sri Lanka Creole Portuguese), such as the dative suffix *-pa*, which was derived from the Portuguese preposition *para* 'for'. Bakker (2003a) reported that this creole has the same set of case markers as the input languages Tamil and Sinhala (Singhalese), but all of them derive from Portuguese forms. The markers are used with a purely Tamil function and usually also in a Tamil position. The problem with relexification is, however, that we often do not find a complete mapping of inventory, positions, meanings, and functions of the substrate morphemes onto the superstrate forms (see Lefebvre (2003) and Siegel (2004b) for some discussion).

Generally speaking, it is largely unclear which kind of process – borrowing, grammaticalization, or relexification – is to be expected in a given contact situation. What is clear is that the different processes and their language-specific combinations lead to diverse patterns in the morphology of pidgins and creoles. On the one hand, there are many pidgins and creoles in which none of the lexifier affixes have survived (e.g., Sranan and Saramaccan), whereas on the other hand, there is a set of pidgins and creoles (e.g., Papiamentu and Haitian) that have preserved (or reconstituted) bound morphemes of their input languages. The latter set of languages refutes the claim that the derivational morphemes of the input languages are lost in creolization and are not reconstituted later (cf. Bickerton, 1988: 278; Jones, 1995: 121; Mühlhäusler, 1997: 169; McWhorter, 1998: 798).

The quite divergent morphological systems and phenomena found in pidgins and creoles have given

rise to a lively debate about which forces shape the morphology of these languages. In general, the question of the emergence of structure in pidginization and creolization is among the most hotly debated issues in the field. Universals of first and second language acquisition, transfer or preservation of features from the input languages, and universal linguistic principles of grammar (such as markedness and iconicity) have all been invoked to account for the characteristics of pidgin and creole grammars and lexicons. The investigation of the morphology has yielded no greater consensus among scholars about the influence of these factors than the investigation of other features of these languages.

What is indisputable is that both the socio-historical settings and the structure, availability, and prominence of the languages present in the contact play an important role. Furthermore, as convincingly argued in, for example, Siegel (2004a, 2004b), the diverse cognitive and socio-linguistic processes involved in language contact and language learning must be taken into account, with contact-induced grammaticalization, language transfer, and dialect mixing and leveling chiefly among them.

Morphology: Optimality Theory

J J McCarthy, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Optimality Theory (OT) is a general approach to modeling human linguistic knowledge (Prince and Smolensky, 2004). OT has had a significant impact on various fields of linguistics, and one of those fields is morphology, the study of word formation. This article discusses how OT provides insight into various morphological phenomena, including affixation, reduplication, and allomorphy. The sections of the article are organized around the several premises of OT that are most directly applicable to morphology: constraint ranking and violability, competition among candidate output forms, faithfulness, and parallelism of evaluation.

Violable Constraints in Morphology

The most important element of OT is constraint violability. Constraints on linguistic forms are ranked in a hierarchy that is specific to each language. A higher-ranking constraint can compel the violation of a lower-ranking one; nonetheless, the violation is always minimal, so no constraint is violated more than is absolute ly necessary to satisfy the constraints that dominate it in the hierarchy. Constraint violability is pervasive in applications of OT, but there are two areas of morphology in which it assumes particular importance: affix location and template morphology.

Affix Location

Alignment constraints demand that the edges of two constituents coincide (McCarthy and Prince, 1993a; Prince and Smolensky, 2004). In particular, a constraint requiring that the left edge of an affix align with the left edge of a word (ALIGN(Afx, L; Wd, L)) or a constraint requiring that the right edge of an affix align with the left edge of a root (ALIGN(Afx, R; Root, L)) will have the effect of declaring this affix to be a prefix. Like all other constraints in OT, alignment constraints are ranked and violable, so an affix's status as a prefix is not absolute it is, rather, contingent on interaction with higher-ranking constraints.

The minimal violation of affix alignment constraints is responsible for several types of infixation. For example, in Timugon Murut (Austronesian, Malaysia), the reduplicative prefix skips over the first syllable if it begins with a vowel (Prentice, 1971), as shown in **Table 1**.

The responsible constraint is ALIGN(RED, L; Wd, L), where RED stands for the underlying form of the reduplicative prefix. This constraint is violated in Timugon Murut because it is dominated by the markedness constraint ONSET (as shown in example 1), which forbids vowel-initial (i.e., onsetless) syllables, as shown in **Table 2**.

(1) ONSET ≫ ALIGN(RED, L; Wd, L)

Morphology: Optimality Theory

J J McCarthy, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Optimality Theory (OT) is a general approach to modeling human linguistic knowledge (Prince and Smolensky, 2004). OT has had a significant impact on various fields of linguistics, and one of those fields is morphology, the study of word formation. This article discusses how OT provides insight into various morphological phenomena, including affixation, reduplication, and allomorphy. The sections of the article are organized around the several premises of OT that are most directly applicable to morphology: constraint ranking and violability, competition among candidate output forms, faithfulness, and parallelism of evaluation.

Violable Constraints in Morphology

The most important element of OT is constraint violability. Constraints on linguistic forms are ranked in a hierarchy that is specific to each language. A higher-ranking constraint can compel the violation of a lower-ranking one; nonetheless, the violation is always minimal, so no constraint is violated more than is absolute ly necessary to satisfy the constraints that dominate it in the hierarchy. Constraint violability is pervasive in applications of OT, but there are two areas of morphology in which it assumes particular importance: affix location and template morphology.

Affix Location

Alignment constraints demand that the edges of two constituents coincide (McCarthy and Prince, 1993a; Prince and Smolensky, 2004). In particular, a constraint requiring that the left edge of an affix align with the left edge of a word (ALIGN(Afx, L; Wd, L)) or a constraint requiring that the right edge of an affix align with the left edge of a root (ALIGN(Afx, R; Root, L)) will have the effect of declaring this affix to be a prefix. Like all other constraints in OT, alignment constraints are ranked and violable, so an affix's status as a prefix is not absolute it is, rather, contingent on interaction with higher-ranking constraints.

The minimal violation of affix alignment constraints is responsible for several types of infixation. For example, in Timugon Murut (Austronesian, Malaysia), the reduplicative prefix skips over the first syllable if it begins with a vowel (Prentice, 1971), as shown in Table 1.

The responsible constraint is ALIGN(RED, L; Wd, L), where RED stands for the underlying form of the reduplicative prefix. This constraint is violated in Timugon Murut because it is dominated by the markedness constraint ONSET (as shown in example 1), which forbids vowel-initial (i.e., onsetless) syllables, as shown in Table 2.

(1) ONSET ≫ ALIGN(RED, L; Wd, L)

Table 1 Timugon Murut reduplication

Basic	*Derived*	*Meaning*
bulud	bu-bulud	'hill/ridge'
limo	li-limo	'five/about five'
abalan	a-ba-balan	'bathes/often bathes'
ompodon	om-po-podon	'flatter/always flatter'

Table 2 ONSET ≫ ALIGN(RED, L; Wd, L)

/RED + abalan/	*ONSET*	*ALIGN*
a. ☞ a-ba-balan	*	*
b. a-abalan	**!	

The choice here is whether to reduplicate an onsetless syllable or to skip over it in search of something more promising. Because ONSET is ranked higher, the latter option prevails.

This analysis highlights a difference between OT and parametric theories of language. Parameters are all or nothing, but in OT, a constraint that is violated remains potentially active because the violation is always minimal. Although ALIGN(RED, L; Wd, L) is violated by the winning candidate *a-ba-balan*, it is still active: it rules out the even more poorly aligned **aba-la-lan*; and it bars the gratuitously unaligned **bu-lu-lud*. Furthermore, even the higher-ranked markedness constraint ONSET is active but violated in Timugon Murut because there are onsetless syllables both initially (*abalan*) and medially (*ambilu.o* 'soul'). Onsetless syllables are marked in Timugon Murut – they are avoided in reduplicative copying – but they are not categorically prohibited because ONSET is ranked below constraints requiring faithfulness between input and output. (Faithfulness is discussed in greater detail later.)

Constraints on affixal alignment have also been applied to clitic and affix order restrictions (Anderson, 1996; Hargus and Tuttle, 1997; Legendre, 2000). For example, the position-class morphology of the Athapaskan languages lends itself to a description in terms of constraints of the ALIGN(Afx, R; Root, L) variety. The prefix that is preferentially closest to the verb root is governed by the highest-ranking such alignment constraint; the prefix that is next closest is governed by a constraint that is next in the ranking; and so on.

Alignment constraints are relevant to the prosody-morphology interface as well. For example, ALIGN (Stem, L; PWd, L) requires that the left edge of a stem coincide with the left edge of a phonological word. This constraint is arguably responsible for the resistance to resyllabification that is observed at the left edges of stems in languages such as German. For example, *ab-arbeit-en* 'to work off' is pronounced [ʔap.ʔar.baj.tən] and not *[ʔa.bar.baj.tən].

Template Morphology

Template morphology refers to those cases in which a morphological category is expressed by imposing a particular syllabic structure on an affix or stem. Partial reduplication is the best-known type of template morphology (*see* **Prosodic Morphology**).

For example, in Diyari (Dieri; Pama-Nyungan, Australia), the reduplicative prefix is disyllabic (Austin, 1981), as shown in Table 3. The reduplicative prefix has its own main stress and always ends in a vowel, as do all phonological words of Diyari. These characteristics show that reduplicated forms have the prosodic structure of compounds, consisting of two separate phonological words, $[t^{j}ilpa]_{PWd}$-$[t^{j}ilparku]_{PWd}$. The analytic problem is to explain why the reduplicative prefix contains exactly two syllables, no fewer and no more.

The reduplicative prefix contains **no fewer** than two syllables because it is a phonological word, and all phonological words of Diyari are minimally disyllabic. Such minimal-word effects follow from independently motivated constraints on prosodic structure: For a phonological word to bear stress, it must contain a metrical foot; and metrical feet are preferentially disyllabic because of the foot-binarity constraint FT-BIN. The reduplicative prefix contains **no more** than two syllables because of other prosodic constraints. PARSE-SYLL is violated by any syllable that is not assigned to a foot, as in trisyllabic $(pína)_{Ft}du$ 'old man.' ALIGN(Ft, L; PWd, L) requires every foot to be initial in a phonological word, so it is violated by noninitial feet, as in $(ŋánda)_{Ft}$ $(wàlka)_{Ft}$ 'to close.' Both PARSE-SYLL and ALIGN(Ft, L; PWd, L) are independently motivated in the stress system of Diyari and other languages.

Neither PARSE-SYLL nor ALIGN(Ft, L; PWd, L) expresses a categorical truth of Diyari. Although these constraints affect the size of the reduplicative prefix, they are ranked in a way that does not allow them to affect the stem or any other unreduplicated word. They dominate the reduplicative identity constraint MAX-BR, which is violated by uncopied segments. But they are themselves dominated by the faithfulness constraint that says every input segment must be preserved in the output (MAX-IO, usually just called MAX). Table 4 illustrates these rankings for PARSE-SYLL. Total reduplication (as in Table 4 line b), reproduces the stem's unfooted syllable, thereby

Table 3 Diyari reduplication

Root	*Word*	*Meaning*
ŋama	ŋama-ŋama	'to sit'
kanku	kanku-kanku	'boy'
ku|kuŋa	ku|ku-ku|kuŋa	'to jump'
t^{j}ilparku	t^{j}ilpa-t^{j}ilparku	'bird species'

Table 4 MAX-IO ≫ PARSE-SYLL ≫ MAX-BR

/RED + t^{j}ilparku/	*MAX-IO*	*PARSE-SYLL*	*MAX-BR*
a. ☞ $[(t^{j}ilpa)_{Pt}]_{PWd}$-$[(t^{j}ilpar)_{Pt}\ ku]_{PWd}$		*	***
b. $[(t^{j}ilpar)_{Pt}ku]_{PWd}$-$[(t^{j}ilpar)_{Pt}\ ku]_{PWd}$		**!	
c. $[(t^{j}ilpa)_{Pt}]_{PWd}$-$[(t^{j}ilpa)_{Pt}]_{PWd}$	***!		

adding a PARSE-SYLL violation. Shortening the stem (as in Table 4 line c), offers another way of satisfying MAX-BR, but it does so at the expense of deleting input material, thereby violating top-ranked MAX-IO. The best option under this ranking is partial reduplication (as in Table 4 line a): It preserves the input stem and accepts a less than perfect copy as the price of avoiding an unfooted syllable.

Timugon Murut and Diyari illustrate a consequence of OT known as emergence of the unmarked (McCarthy and Prince, 1994). Marked structures, such as onsetless or unfooted syllables, may be present in the language as a whole but systematically avoided under certain conditions, some of which can be characterized morphologically. The emergence of the unmarked follows from OT's basic structure: Through ranking, a markedness constraint can be active in a language even when it is not generally obeyed. ONSET in Timugon Murut and PARSE-SYLL and ALIGN (Ft, L; PWd, L) in Diyari are examples of emergent markedness constraints.

Candidate Competition in Morphology

Because constraints are violable in OT, the output of the grammar need not be, and almost never is, perfect in the sense that it obeys all the constraints. Rather, the output is that member of a set of competing candidates that best satisfies the constraint hierarchy of the language in question. An OT grammar therefore chooses from among a set of competitors. Candidate competition offers new insights into many phenomena, among them allomorphy and haplology.

Allomorphy

In generative phonology, it is standard to assume that a morpheme's surface alternants are derived by regular phonological processes from a single underlying representation. There are cases, however, in which this assumption does not hold up. In Catalan (Catalan-Valencian-Balear), for example, the personal article has two forms, *en* before a consonant and *l* before a vowel: *en Wittgenstein*, *l'Einstein*. The surface alternants *en* and *l* cannot be derived from a single underlying form by regular phonological processes – they are simply too dissimilar. Nonetheless, the distribution of the alternants makes sense phonologically, as shown by comparing candidates: *en Wittgenstein* avoids **l'Wittgenstein*'s initial *lw* cluster, and *l'Einstein* avoids **en Einstein*'s initial onsetless syllable. This phenomenon is called phonologically conditioned allomorphy.

The analytic problem presented by allomorphy is this: how can the unpredictability of the allomorphs be reconciled with the predictability of their distribution? The approach to allomorphy developed in OT combines an old idea with a new one. The old idea is that the allomorphs are lexically listed as suppletive alternants (Hudson, 1974). The Catalan personal article has two underlying forms, /l/ and /en/, or /{en, l}/ for short. The new idea is that the same markedness constraints that are responsible for regular phonological processes also choose among the alternants (see Kager, 1996; Mascaró, 1996; Tranel, 1996; Bresnan, 2001; and additional references cited in McCarthy, 2002: 183). The winning candidate is the one that best satisfies the markedness constraints as ranked in the language in question.

Table 5 $*[_{\sigma}lC \gg$ ONSET

/{en, l}+ Wittgenstgein/	$*[_{\sigma}lC$	ONSET
a. ☞ en Wittgenstein		*
b. l'Wittgenstein	*!	

The Catalan constraint hierarchy must favor *en Wittgenstein* over **l'Wittgenstein* as output from /{en, l}-Wittgenstein/. This is accomplished if the constraint against syllable-initial *l*C clusters is ranked above ONSET, as shown in Table 5. The prohibition on syllable-initial *lw* is part of a more general limitation on permissible onset clusters, but for our present purposes it is enough to use the *ad hoc* constraint $*[_{\sigma}lC$. With a vowel-initial stem, such as /{en, l}-Einstein/, the constraint $*[_{\sigma}lC$ is satisfied by both candidates, so ONSET is decisive, correctly favoring *l'Einstein*.

Rule-based or process theories of phonology and morphology emphasize mechanisms of derivation: A rewrites as B in context C. This perspective is unhelpful in allomorph selection, where the mechanism of derivation is trivial, because the allomorphs must be lexically listed. OT, on the other hand, is inherently comparative, using a constraint hierarchy to select the right output from a range of options. Because outputs are chosen comparatively rather than derived by rule, it is possible through ranking for the same constraint to be responsible for allomorph selection in one language and infixation or epenthesis in another. As we have seen, ONSET is an example of such a constraint.

Haplology

In haplology, an affix is absent in a context that is phonologically identical (or similar) to it, for example, /boy-s_{PL}-s_{GEN}/ → *the boys' books*, **boys's*; /Moses-s_{GEN}/ → *Moses' descent from Mt. Sinai*, **Moses's*. An adequate theory of haplology must answer two questions: what causes haplology, and how can an entire affix go missing?

Haplology is to morphology what dissimilation is to phonology. The contextual conditions that encourage haplology – identical or similar speech sounds in close proximity – are the same as those that trigger dissimilation. The only real difference is in what is affected and how. Haplology affects morphemes, which then disappear, whereas dissimilation affects segments, which then change. An example of dissimilation is Latin /popula:lis/ → [popula:ris] 'of the people' (cf. [re:ga:lis] 'royal').

Work in OT supports the idea that the same constraints are responsible for both processes (Russell, 1997; Plag, 1998; Gouskova, 2003). The juxtaposition of identical or similar segments is a marked structure, actively avoided in many languages. Constraints against such structures can force phonological dissimilation or morphological haplology, depending on how they are ranked. The competition between *Moses'* and **Moses's* is abstractly the same as the competition between *popula:ris* and **popula:lis*; in both cases, a markedness constraint forbidding sequences of nearby identical segments is decisive.

Dissimilatory markedness constraints therefore answer for the 'why' of haplology. As for the 'how,' the key insight is that the final [əz] of *Moses'* is doing double duty, serving as part of the root *Moses* and as the genitive suffix (Russell 1997; de Lacy 1999). Haplology, then, is fusion or overlap of morphemic exponence. In haplologized *Moses*,' both root and suffix are fully present, but they use the same segmental material. The competitor **Moses's* avoids this overlap, but at a cost in segmental markedness. When the dissimilatory markedness constraint is ranked higher than the constraint against overlap, the haplologizing candidate wins.

Allomorphy and haplology illustrate the virtue of OT's inherently comparative nature. OT takes the focus off operations and puts it on outcomes. ONSET is as relevant to allomorph selection in Catalan as it is to determining placement of the reduplicative prefix in Timugon Murut. At the operational level, these phenomena are as different as could be, but at the level of comparing candidates, this similarity emerges. Likewise, haplology and dissimilation are operationally distinct, but both reflect similar markedness pressures that become apparent when candidates are compared.

Faithfulness in Morphology

A unique aspect of OT is the idea of faithfulness: the existence of a set of constraints that require identity between the input and output. Faithfulness constraints are generally antagonistic to markedness constraints; the former support lexical contrasts, whereas the latter resist them. A phonological process, such as final devoicing in German /bund/ → [bʊnt] 'federation,' reflects the crucial ranking of a markedness constraint above a faithfulness constraint, favoring an unmarked output structure over fidelity to the input structure.

There have been several proposals to incorporate morphological notions into faithfulness constraints: root and affix faithfulness, morphological polarity and subtraction as antifaithfulness, and constraints on morpheme realization.

Root and Affix Faithfulness

Distinct faithfulness constraints protect distinct properties of the input. For example, MAX requires every input segment to appear in the output, thereby forbidding deletion. DEP, on the other hand, requires every **output** segment to appear in the **input**, so epenthesis violates DEP. The various IDENT(feature) constraints forbid segments from changing their distinctive feature values in the input-output mapping.

Faithfulness constraints are also distinguished by the type of morpheme to which they apply (McCarthy and Prince, 1995, 1999; Beckman, 1999). MAX_{Root} and $\text{MAX}_{\text{Affix}}$ are separate and therefore separately rankable constraints. MAX_{Root} is violated by the deletion of root material and $\text{MAX}_{\text{Affix}}$ by the deletion of affixal material. There is a similar division of the DEP and IDENT(feature) constraints. Universally, MAX_{Root} is ranked higher than $\text{MAX}_{\text{Affix}}$, so roots will in general be treated at least as faithfully as affixes and sometimes more faithfully.

Two sorts of evidence support the distinction between root and affix faithfulness constraints and the universally fixed ranking between them. Evidence from phonological inventories shows that languages often permit certain marked structures to appear in roots but not in affixes. In Arabic, for example, the marked uvular and pharyngeal consonants /χ, ʁ, ħ, ʕ/ are found in roots but never in affixes, which are limited to less-marked consonants such as /t, n, m/. Similarly, in the Cuzco Quechua language of Peru, consonants that are marked by virtue of glottalization or aspiration are allowed in roots but not affixes (Parker and Weber, 1996). In general, if the segments that violate some markedness constraint M are allowed in roots but not affixes, then the language in question must have the ranking $\text{Faith}_{\text{Root}} \gg \text{M} \gg \text{Faith}_{\text{Affix}}$,. In this way, affixes will consistently obey M, but roots need not.

Evidence from phonological alternations also supports the $\text{Faith}_{\text{Root}}/\text{Faith}_{\text{Affix}}$ dichotomy. In Finnish, for example, affix vowels assimilate in backness to a root vowel, but the vowels within a root need not

agree with one another in backness. This means that the markedness constraint that compels vowel assimilation is ranked below IDENT(back)$_{Root}$ and above IDENT(back)$_{Affix}$. Sometimes such effects are preferential rather than absolute. In Emai (Emae; Benue-Congo, Nigeria; Casali, 1998), hiatus is resolved by deleting one of the two adjacent vowels: /... $V_1 + V_2$.../ → [... V_1...] versus [... V_2...]. Whether V_1 or V_2 deletes is determined by the status of the morphemes they belong to: If one is a content morpheme (a root) and the other is a functional morpheme (an affix), then the vowel of the functional morpheme is deleted; otherwise, if the morphemes are of equal status, the morpheme-final vowel V_1 is dropped. The preference for deleting affixal vowels is expressed by the universal ranking MAX$_{Root}$ ≫ MAX$_{Affix}$, although even MAX$_{Root}$ must be violated if a hiatus is produced by the juxtaposition of two roots.

Polarity, Subtraction, and Antifaithfulness

A rather more controversial idea is antifaithfulness, the claim that there is a class of constraints that is obeyed only when a faithfulness constraint is violated (Horwood, 1999; Alderete, 2001a, 2001b). Antifaithfulness constraints have been applied to two of the most thorny problems in morphology, polarity switching and subtraction.

In effect, antifaithfulness constraints say, 'Be different!' and so they are rather well suited to morphological distinctions that involve the reversal of a phonological contrast. For example, in Luo (Nilotic, Kenya), plurality is marked *inter alia* by reversing the voicing of a stem-final obstruent (Gregersen, 1974), as shown in Table 6. The antifaithfulness constraint ¬IDENT(voice) is obeyed when a consonant in the plural disagrees in voicing with its counterpart in the singular. If it is ranked above the faithfulness constraint IDENT(voice) and if other analytic details are attended to, then the final consonant of the plural stem will invert the voicing of its counterpart in the singular.

There are two main types of subtractive morphology: templatic and truncating. In templatic subtractive morphology, the amount of the original stem that remains is constant throughout the morphological category. For example, the vocative forms of personal names in Yapese (Austronesian, Micronesia) are formed by dropping everything except the initial consonant–vowel–consonant sequence (Jensen, 1977), as shown in Table 7. The templatic target in Yapese is the minimal word of the language, and so subtractive morphology of this type is analyzed in the same way as Diyari reduplication.

In truncating subtractive morphology, on the other hand, the amount of the original stem that is dropped is what remains constant. For example, in Koasati (Muskogean, Louisiana and Texas) a class of verbs pluralize by dropping the rhyme (i.e., everything except the onset) of the last syllable in the stem (Kimball, 1986), as in Table 8. In antifaithfulness terms, this type of subtractive morphology is a consequence of the constraint ¬MAX-V, which is satisfied only by candidates in which at least one vowel has been deleted. Additional constraints ensure that truncation occurs at the right edge of the stem and that it also affects a stem-final consonant.

Morpheme Realization Constraints

Occasionally, a language will deviate from its regular phonotactic patterns in a particular morphological category but nowhere else. This phenomenon is usually associated with subsegmental morphology, in which a morpheme consists of one or two distinctive feature values that constitute less than a full segment. Subsegmental morphemes are realized phonologically by autosegmental association with a segment of the stem to which they are affixed (Goldsmith, 1979; Lieber, 1987; Zoll, 1998).

For example, in Javanese (Austronesian, Java and Bali), the morpheme that marks the elative (comparative and superlative) adjective consists of the distinctive feature values [+high, +tense]. This morpheme is associated autosegmentally with the final vowel of the stem (Dudas, 1976), as shown in Table 9. The final vowel of the elative combines the rounding

Table 6 Luo voicing reversal

Singular	*Plural*	*Meaning*
bat	bed-e	'arm/arms'
luθ	luð-e	'walking stick/sticks'
tʃogo	tʃok-e	'bone/bones'
owadu	owet-e	'brother/brothers'

Table 7 Yapese templatic subtraction

Personal name	*Vocative*
luʔag	luʔ
baja:d	baj
maŋɛ:fɛ:lʔ	maŋ

Table 8 Koasati truncating subtraction

Singular	*Plural*	*Meaning*
latáf-ka-n	lát-ka-n	'to kick something'
ataká:-li-n	aták-li-n	'to hang something'

feature of the underlying vowel and the [+high, +tense] features of the elative morpheme, so, for example, /a/ becomes [i] and /ɔ/ becomes [u].

The morphology of the elative interacts in an interesting way with the general phonology of Javanese. In the language as a whole, the tense high vowels /i/ and /u/ are regularly replaced by their lax counterparts [ɪ] and [ʊ] in syllables that are closed by a consonant: /tulis/ → [tulɪs] 'write' (cf. [nulis-i] 'write (LOC)'). Elative forms such as *aŋil* and *abut* are remarkable for having a tense high vowel in a closed syllable, thereby breaking this otherwise inviolate phonotactic generalization of this language.

In a theory where constraints are violable under crucial domination, no phonotactic generalization is necessarily inviolate. The phonology of Javanese as a whole shows that the markedness constraint prohibiting tense vowels in closed syllables, *tnsC]$_\sigma$, is ranked above the antagonistic faithfulness constraint IDENT(tense), as shown in (5). This ranking produces alternations such as *tul*ɪs versus *nulis-i*, as shown in Table 10. The constraint *tnsC]$_\sigma$ is crucially dominated, however, by a special kind of faithfulness constraint that demands the realization of a morpheme that would otherwise disappear entirely (Samek-Lodovici, 1993; Gnanadesikan, 1997; Kurisu, 2002). This constraint, called MORPH-REAL, forces the appearance of a tense vowel in a closed syllable when the alternative is the total disappearance of the subsegmental [+high, +tense] elative morpheme. The ranking is shown in Table 11. Additional constraints rule out other candidates, such as **abt*, where the [+high] and [+tense] features of the elative morpheme are decoupled.

In the emergence of the unmarked, marked structures that are permitted in the language as a whole are forbidden in some limited situations, such as the reduplicative prefixes of Timugon Murut and Diyari. The Javanese elative is, in a sense, the antithesis of that: the marked structure is forbidden in the language as a whole but permitted under specific conditions. The difference follows from the interaction of markedness and faithfulness constraints through ranking. In the emergence of the unmarked, the general faithfulness constraint (e.g., MAX-IO) is ranked above the emergent markedness constraint, thereby limiting its force. In cases such as Javanese, however, the markedness constraint dominates the general faithfulness constraint, but it is overridden only in those circumstances where the more specific faithfulness constraint MORPH-REAL is relevant.

Table 9 Javanese elative

Adjective	*Elative*	*Meaning*
rame	rami	'noisy'
aŋɛl	aŋil	'hard, difficult'
laraŋ	lariŋ	'high in cost'
alʊs	alus	'refined, smooth'
rosɔ	rosu	'strong'
abɔt	abut	'heavy, hard'

Table 10 *[+tense]C]$_\sigma$ ≫ IDENT(tense)

/tulis/		**[+tense]C]$_\sigma$*	*IDENT(tense)*
a.	☞ tulɪs		*
b.	tulis	*!	

Parallelism in Morphology

OT permits, but does not strictly require, a 'flat' derivation, in which the grammar evaluates fully formed output candidates that show the effects of various phonological and morphological processes simultaneously. This parallel view of OT is distinct from the serial derivation of rule-based theories. In its strongest form, parallel OT maps a morphosyntactic input representation directly to the surface form of an utterance. Some implementations of OT are more weakly parallel, positing separate constraint hierarchies for, say, word phonology and phrase phonology (see, e.g., Roca, 1997; Hermans and van Oostendorp, 1999; and the references in McCarthy, 2002: 185).

In a strictly modular, serial theory, all morphology precedes all phonology. If morphology and phonology occur in parallel rather than sequentially, however, then it is possible for derived phonological structure to influence the morphology. Two phenomena that exhibit this behavior are allomorph selection and reduplication.

Parallelism in Allomorph Selection

When allomorphy is phonologically conditioned, the choice of allomorph can be based on the surface phonology rather than the underlying representation of the stem. English supplies a nearby example. The indefinite article has two allomorphs, *a* and *an*. The allomorph *a* is favored preconsonantally by the constraint NO-CODA, which expresses the universal

Table 11 MORPH-REAL ≫ *[+tense]C]$_\sigma$ ≫ IDENT(tense)

/abɔt+ [+high, +tense]/		*MORPH-REAL*	**[+tense]C]$_\sigma$*	*IDENT(tense)*
a.	☞ abut		*	*
b.	abɔt	*!		

markedness of syllables that end in consonants: **an book*. The allomorph *an* is favored prevocalically by ONSET: **a apple*. Clearly, the choice of *a* versus *an* in English bears a more than passing resemblance to the Catalan example discussed earlier.

The selection of *a* and *an* is determined by the surface form of the following word, not its underlying form. In English, underlying /h/ deletes in an unstressed syllable, leading to [h] ~ Ø alternations for some speakers: [hˈɪstəɹiː] *history* versus [ɪstˈɔɹɪkəl] *historical*. Those speakers who have an *h*-less pronunciation of *historical* will most naturally use the *an* allomorph with it: *an historical fact*. Allomorph selection is here being determined by the surface rather than the underlying form, as expected if morphology and phonology take place simultaneously. In a strictly modular theory, allomorph selection could not be affected by the surface properties of syllabification because the syllabification would not yet have been determined at the point in the derivation when the allomorph must be chosen. Modular theories may adopt work-arounds for this problem, such as hanging on to both allomorphs until late in the phonological derivation, but such moves seem more to embarrass than support strict modularity.

Parallelism in Reduplication

There is considerable evidence that reduplication requires access to surface phonological representation. This evidence suggests that the contents of the reduplicative copy are determined in parallel with the surface phonology, and an approach to reduplication in OT has been worked out along these lines (McCarthy and Prince, 1995, 1999).

For example, in Malay (Austronesian, Malaysia), a sequence of vowels and glides following a nasal consonant becomes nasalized (Onn, 1976; Kenstowicz, 1981): /mahal/ → [mãhãl] 'expensive'; /mawas/ → [mãw̃ãs] 'a type of monkey.' As shown in Table 12, this process interacts in an interesting way with reduplication. For expositional purposes, the [w̃ã] syllables of the first example will be referred to as $\tilde{w}\tilde{a}_1$ and $\tilde{w}\tilde{a}_2$: $\tilde{w}\tilde{a}_1\tilde{ŋ}\tilde{ı}$-$\tilde{w}\tilde{a}_2\tilde{ŋ}\tilde{ı}$. The syllable $\tilde{w}\tilde{a}_2$ is nasalized for purely phonological reasons, because it is preceded by the nasal consonant [ŋ]. $\tilde{w}\tilde{a}_1$'s nasalization cannot be explained phonologically, however, because nasality never spreads to the left in Malay: /tahan/ → [tahan] 'withstand,' *[tãhãn]. Rather, $\tilde{w}\tilde{a}_1$ is nasalized because it is a copy of $\tilde{w}\tilde{a}_2$, and $\tilde{w}\tilde{a}_2$ is nasalized. In other words, the reduplicative prefix both triggers the nasalization in $\tilde{w}\tilde{a}_2$ and copies that nasalization.

If reduplication and phonological processes such as nasalization take place in parallel, this kind of behavior is fully expected. Let SPREAD-R(nasal) stand for the markedness constraint that, by dominating IDENT-IO(nasal), forces rightward assimilation of nasality. The overapplication of nasalization seen in reduplicated words shows the effect of IDENT-BR(nasal), a member of the family of constraints introduced in the discussion of Diyari. Table 13 shows how these constraints dispose of the relevant candidates. In keeping with OT's parallel orientation, the output candidates are finished products, showing the results of both nasalization and reduplication. Table 13, candidate b, would be expected on purely phonological grounds, but it is ruled out because it has a fatal disparity in nasalization of *wa* between the reduplicative copy and the stem. Table 13, candidate c's, problem is the failure to conform with the basic phonology of nasalization in Malay because nasality has not spread as far to the right as it can. The winner, then, is Table 13, candidate a, in which the reduplicative prefix both triggers and copies nasalization in the following root.

Table 12 Malay reduplication

Root	*Word*	*Meaning*
waŋĩ	**w̃ã**ŋĩ-w̃ãŋĩ	'odor/many different odors'
hamə̃	**hã**mə̃-hãmə̃	'germ/pl.'
aŋãn	**ã**ŋãn-ãŋãn	'to daydream/id.repeatedly'

Table 13 Overapplication in Malay

/RED + waŋi/	IDENT-BR (nasal)	SPREAD-R (nasal)	IDENT-IO (nasal)
a. ☞ w̃ãŋĩ-w̃ãŋĩ			***
b. waŋĩ-w̃ãŋĩ	**!		***
c. waŋĩ-waŋĩ		**!	*

Conclusion

This article has described various ways in which properties of Optimality Theory can offer new insight into some old morphological problems. Readers should not, however, come away with the view that these are now settled questions. OT is an area of ongoing research and lively debate. Although some aspects of OT are essential to this theory – for example, constraint violability and ranking, candidate competition, and the existence of faithfulness constraints – others are not; and indeed some – such as antifaithfulness and strong parallelism – are quite controversial. For this reason, the main emphasis has been placed on understanding the theory behind OT and the inferences and implications that can be

derived from it. Morphology is one of many areas where OT has offered and will no doubt continue to offer new and surprising insights.

Morphology: Overview

L Bauer, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Morphology is concerned with the relationship between the form of a word and its meaning. For example, if we consider the words *manage, manages, managed, managing, management, manager,* and *managerial* we find that there is a common core of meaning corresponding to the meaning of *manage*, and if we consider the words *managing, obliging, refusing, seeking,* and *teaching,* there is also a common element of meaning (even if it may be quite difficult to specify that meaning precisely) that is reflected in the recurrent *-ing*.

Etymologically, the term *morphology* seems to indicate the study of forms, though it can be seen from the preceding that form alone does not provide an object of study within morphology. Morphologists are not interested in the fact the word *notable* might be considered to contain the orthographic forms *no* and *table* because neither *no* nor *table* as a unit provides any meaning that can be found in *notable*. It is where form and meaning reflect each other directly, either because a certain formal sequence can be seen as being regularly correlated with a particular meaning (as in the examples above) or because there is a regular patterning of semantic relationships, and a particular form can be seen as filling a cell in the pattern. Thus, *worse* is taken to be in the same relationship to *bad* that *bigger* is to *big* or *frailer* is to *frail*, not because of any regularity of form but because of the equivalence of the cells in the pattern or *paradigm*.

Since morphology is concerned with form, it is related to the study of phonology (*see* **Morphophonemics**), and since it is concerned with meaning, it is related to the study of semantics. It is also related to the study of syntax in that many of the meanings that find expression in morphology are related to syntactic function: for example, the comparative, past tense and present participles illustrated above. Morphology is also related to lexis in that morphological patterns can be used in the creation of new lexical items, as illustrated by *manager* and *management* above. This 'cross-road' (Kastovsky, 1977) nature of morphology means that it has been open to influence from phonological and syntactic theories, as well as to changing ideas about the nature of the lexicon. All this is reflected in morphological theorizing.

Morphology: Overview

L Bauer, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Morphology is concerned with the relationship between the form of a word and its meaning. For example, if we consider the words *manage, manages, managed, managing, management, manager,* and *managerial* we find that there is a common core of meaning corresponding to the meaning of *manage*, and if we consider the words *managing, obliging, refusing, seeking,* and *teaching,* there is also a common element of meaning (even if it may be quite difficult to specify that meaning precisely) that is reflected in the recurrent *-ing*.

Etymologically, the term *morphology* seems to indicate the study of forms, though it can be seen from the preceding that form alone does not provide an object of study within morphology. Morphologists are not interested in the fact the word *notable* might be considered to contain the orthographic forms *no* and *table* because neither *no* nor *table* as a unit provides any meaning that can be found in *notable*. It is where form and meaning reflect each other directly, either because a certain formal sequence can be seen as being regularly correlated with a particular meaning (as in the examples above) or because there is a regular patterning of semantic relationships, and a particular form can be seen as filling a cell in the pattern. Thus, *worse* is taken to be in the same relationship to *bad* that *bigger* is to *big* or *frailer* is to *frail*, not because of any regularity of form but because of the equivalence of the cells in the pattern or *paradigm*.

Since morphology is concerned with form, it is related to the study of phonology (*see* **Morphophonemics**), and since it is concerned with meaning, it is related to the study of semantics. It is also related to the study of syntax in that many of the meanings that find expression in morphology are related to syntactic function: for example, the comparative, past tense and present participles illustrated above. Morphology is also related to lexis in that morphological patterns can be used in the creation of new lexical items, as illustrated by *manager* and *management* above. This 'cross-road' (Kastovsky, 1977) nature of morphology means that it has been open to influence from phonological and syntactic theories, as well as to changing ideas about the nature of the lexicon. All this is reflected in morphological theorizing.

Morphology is often viewed in terms of the operations that apply to simpler units (like *manage*) to create more complex ones (like *manager* and *managerial*). This view of morphology is reflected in the articles in this encyclopedia on affixation, backformation, neoclassical compounding, conversion, incorporation, internal modification, morphotactics, and reduplication. It can also be viewed through the notion of related sets of words like *go, went, going,* etc. This is reflected in the article on paradigm.

There are also various problems inherent in morphological study, which are discussed in the articles for inflection and derivation, lexicalization, morpheme, productivity, suppletion, and syncretism. Theoretical approaches to morphology are discussed in a-morphous morphology, autosegmental phonology, declarative morphology, distributed morphology, lexeme-morpheme based morphology, lexical phonology and morphology, onomasiological theory of word-formation, optimality theory in morphology, paradigm function morphology, seamless morphology, sign-based morphology, syntax of words, and template morphology.

Morphological typology and linguistic universals are discussed in some of the articles mentioned above, but also in the articles on morphological typology and morphological universals, and the articles on Arabic as an introflecting language, Chinese as an isolating language, Finnish as an agglutinating language, Italian as a fusional language, and Central Siberian Yupik as a polysynthetic language.

Other aspects of morphology are discussed in acquisition of morphological knowledge during the school years, clitics, dictionaries and inflectional morphology, folk etymology, history of morphology, metathesis in morphology, morphology and language processing, morphology and word formation in corpus linguistics, morphology in pidgins and creoles, splinters, subtraction, and word.

Morphophonemics

R Coates, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Morphophonemics

Morphophonemics (henceforth MP) is an area of considerable complexity. The basic subject matter is easy to grasp; the ways of treating it in linguistic and psycholinguistic theory are what generate the complexity. All MP is a problem for (structural) linguistics, for reasons that will be spelled out below. As an instance of an MP problem, consider the fact that, in English, the word *nature* 'changes' its pronunciation when the suffix *-al* is added; the vowel of the first syllable of *natural* is short, low, and not a diphthong, unlike the corresponding one in *nature*. The scare-quotes around the word 'changes' hint at one of the problematic issues that will be dealt with below. It must be emphasized at the outset that there is no single agreed approach to MP among linguists, and much remains very controversial. It is therefore impossible to avoid a substantial amount of technicality in this article. The term 'morphophonemics' is used in a broader and a narrower sense (the former including the study of phonetically driven regular correspondences or alternations), and it is used in the broader sense here. The range of phenomena that might be covered can best be seen in Dressler (1985: 316–317); MP might include 'changes' in the form of morphemes that may be described by phonetically natural or unnatural rules, by rules that effect fusion between adjacent phonemes or do not, by rules that are subject to grammatical or lexical limitations on their applicability, and by rules describing correspondences that are phonologically unnatural or mere historical residues (Carstairs-McCarthy, 1983: 237–238). An attempt has been made to find a middle way through the competing terminologies used for the phenomena and constructs of MP without dwelling on the differences. The best comprehensive, well-exemplified, introductory survey of MP as a field is Matthews (1991: Chap. 8).

Languages show a great deal of typological difference with respect to MP. Some languages have an immense number of such phenomena, for instance classical Sanskrit and Latin, the Celtic languages, and some Amerindian languages such as Tübatulabal and Yawelmani Yokuts. At the other extreme, there is remarkably little in the indigenous languages of Australia. Others show next to none; a case in point is Vietnamese, it is often claimed. However, even these preliminary comments are problematic, for the very definition of MP, and therefore of what is an instance of it, is linked to the theoretical assumptions one makes. 'Classical Morphophonemics' and 'Post-Structuralist Approaches' of this article roughly follow the historical order of developments within the subject since the 1930s.

The Place of Morphophonemics Within Linguistics

MP is an area of study that sits astride the boundary between the major subdisciplines of phonology and orthography on the one hand and grammar and the lexicon on the other. Its subject matter concerns the fact that the same grammatical or lexical information may be encoded in different ways, phonologically and orthographically, though there are cases of such multiple encoding that are not in the domain of MP as usually understood (see the mention of suppletion below). MP is a phonological and/or orthographical matter in that it studies variation in the spoken or written shape of words, or, more strictly, of individual morphemes (*see* **Morpheme**). It is a grammatical matter in that some, but by no means all, of such variation is a consequence of placing individual words together in grammatically organized structures; and a lexical one in the sense that some of the variation found is a consequence of structuring complex lexical items out of individual morphemes. MP therefore has as its basis the comparison of (1) the shapes that words/morphemes have in different grammatical and lexical

Morphophonemics

Morphophonemics (henceforth MP) is an area of considerable complexity. The basic subject matter is easy to grasp; the ways of treating it in linguistic and psycholinguistic theory are what generate the complexity. All MP is a problem for (structural) linguistics, for reasons that will be spelled out below. As an instance of an MP problem, consider the fact that, in English, the word *nature* 'changes' its pronunciation when the suffix *-al* is added; the vowel of the first syllable of *natural* is short, low, and not a diphthong, unlike the corresponding one in *nature*. The scare-quotes around the word 'changes' hint at one of the problematic issues that will be dealt with below. It must be emphasized at the outset that there is no single agreed approach to MP among linguists, and much remains very controversial. It is therefore impossible to avoid a substantial amount of technicality in this article. The term 'morphophonemics' is used in a broader and a narrower sense (the former including the study of phonetically driven regular correspondences or alternations), and it is used in the broader sense here. The range of phenomena that might be covered can best be seen in Dressler (1985: 316–317); MP might include 'changes' in the form of morphemes that may be described by phonetically natural or unnatural rules, by rules that effect fusion between adjacent phonemes or do not, by rules that are subject to grammatical or lexical limitations on their applicability, and by rules describing correspondences that are phonologically unnatural or mere historical residues (Carstairs-McCarthy, 1983: 237–238). An attempt has been made to find a middle way through the competing terminologies used for the phenomena and constructs of MP without dwelling on the differences. The best comprehensive, well-exemplified, introductory survey of MP as a field is Matthews (1991: Chap. 8).

Languages show a great deal of typological difference with respect to MP. Some languages have an immense number of such phenomena, for instance classical Sanskrit and Latin, the Celtic languages, and some Amerindian languages such as Tübatulabal and Yawelmani Yokuts. At the other extreme, there is remarkably little in the indigenous languages of Australia. Others show next to none; a case in point is Vietnamese, it is often claimed. However, even these preliminary comments are problematic, for the very definition of MP, and therefore of what is an instance of it, is linked to the theoretical assumptions one makes. 'Classical Morphophonemics' and 'Post-Structuralist Approaches' of this article roughly follow the historical order of developments within the subject since the 1930s.

The Place of Morphophonemics Within Linguistics

MP is an area of study that sits astride the boundary between the major subdisciplines of phonology and orthography on the one hand and grammar and the lexicon on the other. Its subject matter concerns the fact that the same grammatical or lexical information may be encoded in different ways, phonologically and orthographically, though there are cases of such multiple encoding that are not in the domain of MP as usually understood (see the mention of suppletion below). MP is a phonological and/or orthographical matter in that it studies variation in the spoken or written shape of words, or, more strictly, of individual morphemes (*see* **Morpheme**). It is a grammatical matter in that some, but by no means all, of such variation is a consequence of placing individual words together in grammatically organized structures; and a lexical one in the sense that some of the variation found is a consequence of structuring complex lexical items out of individual morphemes. MP therefore has as its basis the comparison of (1) the shapes that words/morphemes have in different grammatical and lexical

contexts and (2) the shapes that morphemes have in different but related lexical items. As to (1): many Italian words such as the noun *amico* 'friend' (plural *amici*) have a stem that varies in pronunciation–here, between /amik-/ (singular) and /amitʃ-/ (plural); and as to (2): the English verb *describe* /dɪskraɪb/ has as its counterpart the noun *description* where the related stem is pronounced /dɪskrɪp-/.

In terms of the standardly recognized subdisciplines of linguistics, MP has been reckoned by some as part of morphology, though, for reasons that will become apparent below, it (or a substantial portion of it) has been reckoned to be part of phonology (*see* **Phonology: Overview**) in Generative Phonology (*see* **Generative Phonology**) and approaches derived from or influenced by this movement. The view is taken here too – and it was taken by a figure so early in the history of linguistics as Baudouin de Courtenay – that some instances of MP alternation are truly phonological while the rest are morphological. This is not especially controversial, but it does entail that a language's MP is not a unitary collection of phenomena. A useful summary of whose work regards MP as part of phonology, as part of morphology, and as a hybrid is given by Dressler (1985: 1–10). An extended history of MP is given by Kilbury (1976), and Dressler's book extends this still further. The account below restricts itself to matters of pronunciation, in accordance with the strictest interpretation of the term MP. Much of interest could be said about spelling variation of parallel and equivalent type; however, much of this would simply reiterate what is said about MP in relation to a different medium. 'Orthographic MP' could be termed morphographemics, though this term has no very widespread currency, largely because the orientation of most modern linguistics leans toward speech, not writing, and tends to bypass the entire issue.

This field of study should be very clearly distinguished from that branch of morphology, inflectional morphology, which studies variation in word form expressing difference of grammatical function; variation such as that exemplified by *dust*, *dusts*, *dusted*, *dusting* or *mensa*, *mensam*, *mensae*, etc., is not a question of MP. The 'endings' or inflectional elements in these words each express a different grammatical meaning (or set of meanings); the individual elements themselves show no variation in shape.

Classical Morphophonemics

MP and Structuralist Linguistics

The term 'morphophonemics' and its relatives 'morphophonemic' and 'morphophoneme' originated in structuralist linguistics. This survey opens with an account of the phenomena in structuralist terms, though a stance free of any party line is adopted further on. The term in this form was used in the American branch of this movement. The European school, exemplified particularly by Trubetzkoy (1931), preferred the term 'morpho(pho)nology' for essentially the same concept, but Trubetzkoy included some matters that are not regularly attributed to MP these days, and these are omitted here. Dressler (especially 1985) uses the variant term 'morphonology' to denote the collection of phenomena that he sees as produced by semiotically natural interactions between phonology and morphology, which corresponds closely with the subject matter envisaged by Trubetzkoy. The concept of MP, though not the word, can be traced to the work of early phonologists in Russia, especially Baudouin de Courtenay and his pupil Ščerba; indeed, the differences between these two scholars can be seen replicated in the history of American linguistics sketched below.

Alternation

The account of MP given below is centered, purely for expository reasons, around the American usage. Understanding it depends on the prior identification of the phonemes (*see* **Phoneme**) of a language and of the morphemes (*see* **Morpheme**) or minimal meaning units that are realized by strings of phonemes. Thus the word (consisting of a single morpheme) {turnip} is realized in many accents of British English by the string of five phonemes /t, ə:, n, ɪ, p/. The morpheme bearing the grammatical meaning 'gerund' is realized by the two-phoneme string /ɪ, ŋ/. The methodology of structuralist analysis requires us to proceed 'upward' from the identification of phonemes to the identification of morphemes. A consequence of this procedural requirement is that many a morpheme is analyzed as having more than one phonological shape. For instance, it is clear that /d/ and /s/ are distinct phonemes of English, in that they distinguish pairs of words like *raid* and *race*, *deal* and *seal*. Yet they do not have this word-distinguishing function when we come to examine the strings /ɪveɪd/ and /ɪveɪs/ (in one variety of British English, Received Pronunciation). The former represents the word *evade*, and the latter represents the first element in the word *evasive* (the second element being the adjective-forming suffix *-ive*). It is clearly reasonable from the semantic point of view to argue that /ɪveɪd/ and /ɪveɪs/ bear the same meaning, and represent the same linguistic unit; and that /ɪveɪs/ is (loosely speaking) just the form of /ɪveɪd/ that is used when it appears in a derived adjective. When a linguistic unit has more than one shape in this way, it is said to *alternate*, and its various shapes

are called *alternants*. In the present case, the morpheme {evade} has two alternants; alternants of a morpheme are called *allomorphs* (cf. and contrast the concept allophones of a phoneme). In its classical sense, then, MP is the study of the relations between phonemes that are involved in alternations of this kind.

If such alternations were casual and unsystematic, MP would not be very interesting. It would involve making a list or catalog of pairs (triples, etc.) of allomorphs and that would be that. Such an approach is technically called an item and arrangement (IA) approach to MP, i.e., the items or allomorphs are simply stated along with their pattern of distribution or arrangement in relation to other linguistic units. This notion contrasts with item and process description (see further below), in that IA presupposes no directionality of relationship between the alternants; the synchronic relation is not stated as one where one alternant replaces another, or where one is basic. Such an approach is commonly thought especially suitable for the statement of alternations that are of restricted frequency in a language. There are indeed cases of allomorphy that are isolated in their language; for instance, the relation between the vowels in the semantically related word(-stem)s *broad*, *bread(th)* in English is unique. The morphophonemic relation between /ɔː/ and /e/ is realized only in this pair of words. IA has of late been less favored as a descriptive technique where there are many parallel and/or similar alternations. As originally formulated, it was a descriptive technique rather than a theory; as such it can, of course, be made to work, but has fallen out of favor since the mid-1960s where linguistic theorizing has been a dominant concern and generalizations have therefore been thought more interesting than disconnected facts. It was, especially in the period from ca. 1967 to 1980, widely believed that IA accounts could not express generalizations in a revealing way within many then-current theoretical models. This is because, in classical structuralist methodology, alternations were treated essentially as properties of individual morphemes rather than as wider-ranging phonological correspondence sets; or rather the process of analysis involved identifying alternation in one morpheme, establishing a morphophoneme (see below), and generalizing its use to other morphemes. This is what the leading structuralist Zellig Harris said explicitly (1951: 219); he also introduced the notion of MP as having to do with "irregular [sic] phonological alternations," by definition. But it would be unfair and even illogical to conclude that it is totally impossible to express such generalizations within an IA account permitting some extraction of regular correspondences. What is said below about via rules has a strong affinity with IA-type descriptions.

In fact, MP alternations are very frequently recurrent. The relation between /d/ and /s/ that we noted above recurs in the following pairs of semantically related English words (in Received Pronunciation [RP]): *allude/allusive*, *elude/elusive*, *invade/invasive*, *corrode/corrosive*, *divide/divisive*, *explode/explosive*, *exceed/excessive*, *expend/expensive*, and so on. We can express such mass correspondences as morphophonemic generalizations, e.g., that stem-final /d/ word-finally alternates with /s/ where the suffix /ɪv/ follows. (Actually, further conditions would need to be built in for strict accuracy. For instance, *attend/attentive* is an irregularity within this phonologically defined group of words. But the point to note here is simply that a definable recurrent pattern exists, even if it is not exceptionless.)

Notice that these relations appear under conditions that are not entirely to do with pronunciation. While /sɪ/ appears to replace /dɪ/ in the cited forms, nothing about English phonology makes the sequence /dɪ/ illegal; it is pronounced in a host of words like *dip*, *edition*, *additive*, *recordist*.

It is illegal only when the /ɪ/ belongs to a suffix; and, more specifically still, that suffix must be /ɪv/. It is legal in otherwise analogous cases such as *record-ist*, *winding*, *acid-ic*, *nud-ity*. Thus the alternation between /d/ and /s/ is triggered by a detail of word structure and not of phonology. This is entirely typical of MP. Sometimes the triggering factor is grammatical. Some words ending in /ŋ/ add a /g/ (i.e., /g/ alternates with zero) in RP; but only before a suffix /ə/, and only when they are adjectives and when that suffix is the comparative suffix: *young-er*, *strong-er*, *long-er*; contrast *sing-er*, *hang-er*, which are nouns, with a phonologically identical but grammatically different suffix.

Some MP, however, occurs under much more strictly phonological conditions (allowing as 'phonological' information the positioning of word and morpheme boundaries). Numerous languages, including Polish, Russian, Dutch, German, vernacular Turkish, Mandarin Chinese, and Korean, have a contrast between voiced and voiceless or between unaspirated and aspirated consonants, except in word-final position (and some others that need not concern us). If this restriction is a structural one, then there is no MP; thus in Mandarin Chinese, no syllables ever end in a voiced obstruent (i.e., stop, affricate, or fricative), and since lexical stems in Mandarin may be thought of as realized by single syllables, and words as comprising strings of one or more stems, it follows that no words end in a voiced obstruent either. In other languages, the matter is different. It may be that the restriction on voiced consonants in word-final

position does not apply to stem-final position, and that stem-final position need not coincide with a syllable boundary; in which case there may be alternation between consonants at that position for any stem to which vowel-initial affixes may be added. For instance, in Russian /t/ and /d/ generally contrast (e.g., *doska*, *drok* vs. *toska*, *trok*), but the word *god* 'year' is pronounced /got/ in isolation while its alternative nominative-case plural forms both contain a /d/: /goda/ or /gody/. Many other words show parallel behavior: /t/ and /d/ are therefore in a morphophonemic relation in such words. European structuralists would say that the consonant at the end of such words as *god*, *l'od*, *sad*, *trud*, etc. is an archiphoneme consisting of the intersection of the distinctive features (*see* **Distinctive Features**) defining /t/ and /d/; i.e., nonnasal dental stop consonant, with no specification for voiced/voiceless. In Russian, it happens to be phonetically voiceless; but phonologically speaking, it is neither voiced nor voiceless, since the contrast or distinction between these two feature values is inoperative in this position.

Using an archiphoneme, which is an underspecification (*see*) of the phonemes involved in the morphophonemic relationship, is the first technique we will note for describing sets of alternating phonemes as a linguistic unit at some level. Hudson (1980) provides a reductivist demonstration of how archiphonemic representations can provide an integrated account of all regular MP phenomena, at the cost of some psychological plausibility where the conditioning factors are not purely phonetic. Outside Hudson's work, the technique has generally been thought unsatisfactory in those cases where the phonemes involved are not closely related phonetically or where a phoneme alternates with zero. Harris (1951: Chap. 14) was, however, prepared to use special symbols covering some phoneme and its absence; for instance he transcribes /sɪmpL/ (Harris, 1951: 239) for the morpheme {simple}, pronounced /sɪmpl/ in isolation and /sɪmp/ before the adverbial suffix /li/. This, and other U.S. structuralists' morphophonemes, which are just cover symbols for alternating phonemes, should not be confused with archiphonemes, for the morphophonemes do not necessarily have unitary phonetic feature content – despite what Harris asserts (1951: 219); the example given, /L/, cannot be the intersection of the phonetic features of /l/ and zero, but must actually be their disjunction. In practice, they are just names for sets of phonemes. Archiphonemes are defined as having some real featural content. Hudson's approach sets out a way of combining these two notions, however.

Some American analysts, it should be noted, used morphophonemes of a rather different character. For instance, Swadesh and Voegelin (1939), describing the phonology of Tübatulabal, employ symbols that represent simultaneously a phoneme and an effect of that phoneme on adjacent phonemes; their /N/ is an [n] that has the effect of shortening preceding vowels even where those vowels, for prosodic reasons, might be expected to be long. This descriptive technique is anomalous within the more simplistic varieties of structuralist linguistics, and has something in common with Prosodic Phonology as developed by J. R. Firth and his associates, because the phenomenon is not confined within the boundaries of a phoneme considered as one of a sequence of 'vertical slices' in the flow of speech. This – and especially a related work by Bloomfield (1939) on Menomini – has been championed as a precursor of the technique of Generative Phonology (see below), but strictly that is not the case.

Nonsegmental MP

The entire discussion so far has been in terms of alternation between segments, for these are the phenomena that have been understood as prototypical MP. But it is completely thinkable that suprasegmental aspects of pronunciation, i.e., stress and tone, could alternate in similar ways. Similar to the regular alternations such as that involving word-final obstruents in Russian is the so-called rhythm rule of English. This may operate when two stressed syllables come to be adjacent to each other in running speech; if the first is in a noun's premodifier (usually a compound adjective, a noun, or a numeral), stress shifts back by one or more syllables if there is a suitable site to accommodate it within the premodifier. (There are phonological restrictions on what may qualify as a site, but these may be taken for granted here.) For instance, stress is on the final syllable in the words *sixteen*, *hard-boiled*, *Tennessee*, *canteen*, pronounced in isolation, but shifts back by one or more syllables when one of these words precedes a word bearing initial-syllable stress, as in *sixteen years*, *hard-boiled egg*, *Tennessee Williams*, *canteen manager.*

Tone languages often show variation in tone-form paralleling the segmental MP that was discussed above. A straightforward instance occurs in Mandarin Chinese. This language has four lexical (distinctive) tones, as diagramed in Table 1.

Tone 3, however, has a shape indistinguishable from that of Tone 2 when it occurs before a word also bearing Tone 3. Thus the words *hěn* 'very' and *hǎo* 'good' both have lexical Tone 3; but when occurring together in the phrase *hěn hǎo* 'very good', 'okay', *hěn* appears to bear Tone 2. Similarly in Yoruba, a language with three distinctive level tones (low, mid, high), sentence structure requires what

Table 1 Contrasting tones in Mandarin

jī	jí(le)	jǐ	jì
'chicken'	'extremely'	'how many?'	'to remember'
Tone 1	Tone 2	Tone 3	Tone 4

immediately precedes a finite verb to have a high tone, irrespective of the tone this material would have in isolation. Thus *baba* 'father' has lexical mid tones on both syllables, but in *babá túndé* 'father comes again', the second syllable of *baba* has a high tone. These Mandarin and Yoruba instances might be thought of as tone-sandhi (see below for sandhi). Tonological apophony (see below for discussion of this term, including of whether it is really a form of MP) may also be found. In Longunda, there is no difference between the segmental makeup of the first-person noninclusive and that of the second-person pronouns (there are several pronouns in each category); but the former all bear high tones and the latter low tones. In several Bantu languages, relative clauses are marked (to simplify somewhat) by overall lower pitch than the same material when used as main clauses. Pitch range is raised in Mandarin to indicate certain types of question.

Regular Accommodations

In many languages, regular accommodations take place where morphological operations have brought together certain strings of phonemes. These accommodations are often called morphophonemic in the narrow sense, synchronically motivated or automatic; though the last term is misleading if it suggests that the speaker necessarily adjusts his/her pronunciation during the course of production. For instance, in English, /m/, /n/, and /ŋ/ are distinct phonemes (cf. *ram*, *ran*, *rang*; *hammer*, *Hannah*, *hangar*); but wherever prefixes ending in /n/ occur before a stem beginning with a consonant of a different place of articulation (let us concentrate on labials and velars), a replacement of the alveolar articulation by a labial or velar one has taken place. Before a vowel, two such prefixes might be pronounced /ɪn/ and /∧n/, as in *inadmissible*, *unacceptable*; before /p/, /b/ they are pronounced /ɪm/, /∧m/, as in *impossible*, *unbelievable*, and before /k/, /g/ they are pronounced /ɪŋ/, /∧ŋ/, as in *incredible*, *unguarded*. (Some anglophone readers may be totally in agreement only in the case of *impossible*, where the claim is backed up by the spelling; that will be sufficient to establish the point, however. Some readers may make the other accommodations only in fairly rapid speech, but nevertheless do so. We return to the question of rapid speech effects and their relation to MP below.)

The Transition to Nonstructuralist Approaches

The traditional description of Sanskrit developed by Hindu scholar-priests in India includes highly systematized rules, effectively MP rules, for adjusting the shape of stems according to the phonological properties of the adjacent word or morpheme (the rules of external and internal sandhi, respectively; the English example at the end of the last section is a case of internal sandhi). An instance of external sandhi in Vedic Sanskrit is as follows: words pronounced in isolation with final voiceless consonants appear with a voiced consonant of the same position of articulation (where the following word begins with a voiced sound (including vowels but excluding nasals), and with a nasal consonant of the same position of articulation where the following word begins with a nasal consonant. The same is true in internal sandhi, i.e., within morphologically complex words. But in Vedic Sanskrit the rules of internal and external sandhi are not precisely identical. In words ending in *-r*, the /r/ is preserved within lexical items in compounds like *ahar-páti* 'day-lord', while *áhar* 'day' used independently would appear with final so-called *visarjanīya*, rendered <h>, if the following word began with /p/. (The precise nature of *visarjanīya* is debatable, but for present purposes the only crucial point is that it is **not** realized as [r].)

This Sanskrit example shows alternation between sounds, or rather phonemes. Let us examine a further example where there is alternation between a sound and its absence, so to speak. The familiar *liaison* of French is a matter of sandhi, as just defined; but here, in the principal instances, /z/, /n/, and /t/ are variably present or absent. Concentrating on /z/: this phoneme may serve as a realization of the grammatical category {plural} As such, in the definite article *les* it alternates with zero, in external sandhi, under strictly phonological conditions (allowing word boundaries to be such, as above), namely depending on whether the word following begins with a vowel or a consonant: *les oeufs* /lez ø/, *les choses* /leʃoz/. It also alternates in more complex ways under partly grammatical conditions. It is obligatorily present in plural adjectives that precede the noun within the noun phrase (*de grands arbres* [də grãz arbr]) and in pronouns preceding the finite verb (*elles ont* . . . . [elz õ . . . .]); but only variably present between the noun and a following adjective within the noun phrase (*des tourments affreux* [de turmã(z) afrø]) and between a noun phrase (not consisting merely of a pronoun) and the finite verb (*mes parents ont* . . . .[me parã(z) õ . . . .]); and scarcely ever in conjuncts before the word *et*. (The account just given is idealized to some degree; individual French speakers differ widely in their application of these informal rules.)

Traditional accounts of these two sets of phenomena by Indian and French grammarians do not treat the alternants as being of equal status. The Sanskrit data are customarily presented in terms of sandhi rules applying to pausal forms, i.e., forms used in isolation or before a pause. The French data are, by conservative analysts, usually described in terms of the omission of /z/ in certain circumstances. All the above therefore may be used to exemplify a second possible descriptive technique for handling the alternations involved in MP in terms of 'underlying' units (as opposed to mere sets of alternants; see above). It consists of taking one of the alternants and treating it as basic in relation to the other(s) (for the issues, see Matthews, 1991: 146). The other(s) must then be derived from it by means of transformational rules changing the nature of the alternating element(s). One might, for instance, decide that /ɪn/ was the basic form of the English negative prefix referred to above, and have a rule changing it into /ɪm/ or /ɪŋ/, depending on the pronunciation of the element immediately following. In a fully integrated linguistic description, it is generally reckoned most desirable for all elements showing similar behavior to be handled in the same way in this respect; thus if /ɪn/ were chosen as basic, then /ʌn/ rather than /ʌm/ or /ʌŋ/ would no doubt be chosen as the basic form of the other prefix, meaning that the same rule of phonological adjustment could serve to derive the range of forms seen in both prefixes. The same would go for such other possible elements in English as *non-*, *con-*, *syn-*, *pan-*, and so on.

Some Considerations from the Perspective of Language Change

The evidence of language change suggests that there is some historical justification for the idea that one alternant is more basic than the other(s) in elements that alternate. The present state of knowledge on this matter is summed up in Witold Mańczak's second 'tendency' of analogy, which states that, at least as far as the stems of words are concerned, alternation is more often abolished than introduced, i.e., one of the alternants is generalized into positions formerly occupied by others. A simple instance involves the English word *old*, from Germanic *[ald], which originally had a comparative and superlative form *elder*, *eldest*, developed by regular and explicable phonetic change from an earlier *[aldiro], *[aldist-], but these are now retreating before the forms *older*, *oldest*. It is a commonplace finding that basic forms tend to replace the others in such cases. A partial explanation may be sought in the tenets of Natural Morphology (*see* **Natural Morphology**), associated with W. Mayerthaler. But there is room for debate about what criteria should be involved in deciding which forms are basic. The case of *old* is mercifully straightforward; it is reasonable to argue both on morphological grounds (it is unsuffixed) and on semantic grounds (it shows only the positive degree of comparison) that *old* is more basic than *eld-*. Many similar cases can be found (cf. e.g., Hock, 1986: Paras. 9.1.1, 9.1.4; Romaine, 1983). They are usually termed cases of analogical leveling. (Readers with a knowledge of historical linguistics may note that Jerzy Kuryłowicz's second 'law' of analogy, that basic forms are replaced by derived forms, seems to pull in the opposite direction from the claim just made; but Kuryłowicz's law is best seen as a condition on proportional analogy and not on straightforward leveling of the kind just cited.)

A further possible basis for the elimination of alternation is the generalization of the allomorph most frequent in actual usage, as opposed to the basic one (as defined above). MacWhinney (1978) provides good psycholinguistic documentation for this over a good range of languages, and historical linguists have long suspected that it takes place.

Post-Structuralist Approaches

Within the framework called Generative Phonology (*see* **Generative Phonology**), the descriptive technique discussed in the previous paragraphs using English, Sanskrit, and French examples is accommodated rather naturally. The theory requires that, in the overwhelming majority of cases, a unique underlying form or underlier be chosen as the lexical representation of the set of allomorphs representing a morpheme. In the easy cases, the chosen underlier is one of the alternants (though not necessarily the most 'basic' one in any sense of the word *basic* that relies on semantic criteria). The underlier is then reconnected to the actual pronunciations by a block of statements called (process or transformational) *rules* effecting changes in phonetic/phonological feature content. Sometimes the underlier may consist of a string of phonemes not all of which occur in any one allomorph, i.e., the underlier may be form-abstract (see Coates, 1987: 40). Here is an example, adapted from Anderson (1974: 141–144; it is actually part of a rather more complex argument there). In Icelandic, Anderson suggests, it is defensible to select as underliers for the stems of the lexical items 'kettle' and 'gods' the forms /katil/ and /ragin/, respectively. These words appear in different case forms, realized suffixally. Anderson justifies analyzing the vowel of the first syllable as /a/ in the light of the genitive plural forms *katla* and *ragna*; we will simply accept this for the purposes of the discussion (Table 2).

There is rather more to this example, in fact. A few moments' exercise with a pencil and paper will reveal

Table 2 An illustration of the operation of MP rules in Icelandic

katil + r	katil + um	ragin + ZERO	ragin + um	Underliers
katil + r	katl + um	ragin +	ragn + um	Rule deleting vowels in stem-final syllables where a vowel follows in the next
katil + r	kötl + um	ragin +	rögn + um	Rule converting [a] to [ö] before [u] in the next syllable
ketil + r	kötl + um	regin +	rögnum	Raising of [a] before [i] in the next syllable
ketill	kötlum	regin	rögnum	Actual pronunciations, after other minor adjustments

that stating the three key rules in the order given is not an arbitrary matter. If the rules, as formulated, were allowed to apply in some other order, their output would not be the actual forms found in Icelandic. None of the forms cited could be affected by the second rule if it applied before, and only before, the first. And if the third were to apply first, the second would find no forms to apply to. The notion of ordering relations among rules is therefore introduced (cf. **Rule Ordering and Derivation in Phonology**). Such a block of rules may or may not be extrinsically ordered, i.e., be obliged to be applied in a particular sequence, depending on which of the variants of Generative Phonology is being considered. Various principles have been proposed that might dispense with the necessity to stipulate a particular order of application. For instance, in relation to the Icelandic data above, one might argue that if all the rules mentioned were deemed at the outset to be relevant to the forms potentially undergoing them, then the first rule (vowel elision) must precede the other two to ensure that all three are operative; no special stipulation of order needs to be made, therefore. Adherence to particular principles of such a kind was one of the main marks of belonging to the various subschools of Generative Phonology. There is fuller discussion of this point under rule ordering (**Rule Ordering and Derivation in Phonology**).

A unique underlier is chosen in accordance with the (psycholinguistically not fully supported) principle that economy in the lexicon is to be maximized (as opposed to, for example, economy in the number of rules needed to produce representations of actual pronunciations, or economy in the number of ways in which these are permitted to interact). Obviously, the nature of the rules that need to be formulated is dictated by the choice of unique underlier, and the need for rules in any case is dictated by the requirement of having such a unique underlier.

In some, particularly earlier, variants of Generative Phonology, a considerable degree of abstraction was tolerated. In terms of the present discussion, this means that the underlier was not required to actually be one of the alternants, nor to consist exclusively of segments found in the set of alternants (as is the case in the Icelandic example above). The underlier could contain abstract (i.e., nonoccurring) segments, especially if their selection resulted in some overall economy in the grammar of the language being described. A celebrated instance of this, much discussed and rediscussed, was the group of alternations in English produced by the late medieval pronunciation changes called the Great Vowel Shift. Their precise phonetic nature is not important here, but their effects are. In collaboration with a rule of vowel shortening applying in the antepenultimate syllable of words having at least three syllables, they produced alternations such as those heard in the stems of the following word pairs: *alkaline/alkalin(ity)*, *obscene/obscen(ity)*, *sane/san(ity)*. Champions of the classical variant of Generative Phonology postulated as underliers for these pairs of stems not one of the occurring alternants, but a form in which the crucial vowel was a kind of compromise between the two occurring ones. Respectively, these were /i:/, /e:/, and /æ:/; long in duration like the diphthongs in the adjectives, but of an articulatory quality more resembling the short vowels in the nouns. In that sense, the symbol representing the alternating pair of vowels was an abstract entity. These objects, called systematic phonemes by generativists, were essentially morphophonemes in the sense of being representations, in the guise of units, of the alternations in question. This notion of systematic phoneme should be compared and contrasted with the notion archiphoneme introduced above. Both notions are attempts to solve the problem of phoneme sets which, under particular circumstances, do not do their primary job of distinguishing pairs of words. Within GP, systematic phonemes were the 'phonological' units of lexical representation, and lexical representations were therefore encoded at a **level** of MP (Spencer, 1991: 53–55). Although the concept was foreshadowed in earlier structuralist work, in structuralist analysis any MP 'level' was a consequence of analytic procedures and had no important theoretical status.

In developed Generative Phonology, the term 'systematic phoneme' was understood rather more broadly, but the origin of the notion was in the representation of alternation, as just outlined. This analytical technique was pushed to its limits by a few linguists such as Lightner (1983), who was content, in his synchronic phonology, to link such (historically distantly related) English word pairs as *wolf/lupine*,

three/ternary (1983: 151–155 and especially 184–186), by a single phonologically specified underlier, i.e., a string of systematic phonemes. The result of this was immensely complicated phonological descriptions containing many rules with little generality (i.e., they are lexically triggered) or psychological plausibility (i.e., the complexity is not revealed by extended processing time in experiments). In reaction to such attempts, some theorists tried to limit the power of generative phonologies by restricting the systematic phoneme to the job of capturing of regular and phonetically natural alternations; e.g., Kiparsky with his alternation condition (1974) and Hooper with her true generalization condition (1976: 13ff). Other suggested restrictions precluded the use of abstract segments in underliers, i.e., segments that never show up in actual phonetic forms in the language being analyzed. All of these tendencies pushed in the direction of making (process) rules generally applicable rather than lexically triggered, and making them correspond quite closely with the operations seen in phonetic change. For reasons well set out by Bauer (2003: 155–156), it is hard to find common ground in which a compromise position between analysts for and against phonological abstractness can be worked out, but Bauer himself has consistently (e.g., 1983: 133–139, 2003: 157) emphasized the importance of productivity as a concept in morphology and championed the idea of a level of lexical representation just sufficiently abstract to allow all productive phonological processes to apply to it in the guise of general (essentially phonetically natural) rules. There is a clear relationship, but by no means one of identity, between productive processes and phonetically natural ones.

The generative approach just outlined is an instance of what has been called the item and process (IP) approach to MP (contrast IA introduced above). The item in question is the chosen underlier, and the process or processes are the rule(s) formulated to convert it into the full range of actually occurring alternants.

Debate in Generative Phonology after the formulation of the above ideas in the mid-1960s was, in most cases, of a technical kind concerning, for example, whether some kinds of rules/processes are restricted to operating at certain postulated levels or strata of the phonological system of a language (or of languages in general), such as those defined by particular patterns of affixation (surveyed by Bauer, 2003: 174–191), or whether systematic phonemes need to contrast in distinctive feature specifications at the lexical level; or concerning what degree of abstraction is permissible in the choice of underliers. (For some such developments, *see* **Lexical Phonology and Morphology**, and Lieber, 1987: 72–129, 145–150.) None of this queries the fundamental nature of MP rules under the IP interpretation outlined above: they are formal devices for changing the value of some phonetic/phonological feature into some other value, and thereby 'changing' the pronunciation of the segments embodying the feature in the phonetic environment specified in the rule. Some critical discussion on the periphery of this mainstream approach has raised interesting questions, however. Proponents of Natural Generative Phonology (especially Hooper, 1976) canvassed the wider use of rules simply associating pairs of allomorphs (via rules) rather than claiming, and expressing by means of a common underlier, a deeper unity (as with the minor rules of the 'classical' model; in NGP, 'classical'-style MP rules were restricted to the expression of exceptionless, and in practice usually phonetically natural, alternations. In effect, this claim meant that alternations having some currency in the lexicon, while not being fully regular, had more in common with suppletion than with regular alternation. (Suppletion is the relation holding between grammatically related but phonologically totally distinct word forms, such as *go* and its past tense form *went*, or between the corresponding French word forms *va/vais* and *allais* and the future tense *ira*, etc.) The claim of an intimate relation between suppletion and all nongeneral MP processes is made explicit in Hudson (1980). Zwicky (1986) also makes an important qualitative distinction between productive rules and fossilized allomorphy and assigns them to different analytic levels or strata with different properties. Fossilized allomorphs are chosen in particular contexts; the basic form appears by default in others, and (relatively) general MP rules apply to the output of this first analytic level. The relatively arbitrary link between forms related in nonproductive ways, expressed very much like (generalized) IA statements (see above), could be seen as accounting for Mańczak's second 'tendency' of analogy, discussed above; the bonds between allomorphs, because arbitrary and not directional in any phonological sense, could be easily dissolved and one member of the pair (or n-tuple) be promoted at the expense of the other(s).

Within the context of the debate about the overall structure of linguistic theory in the generative paradigm, Per Linell's (1979) typology of MP rules can be seen as building on the antiabstract direction embarked on by NGP theorists such as Vennemann and Hooper. This interesting work, with enduring consequences, emphasizes that numerous psychologically distinct phenomena were not properly distinguished in the theoretical apparatus of Generative Phonology. In particular, Linell distinguishes phonotactic rules from morphophonemic rules proper. The

former correspond essentially to what in this article are called phonetically natural rules, and the latter to the residue, including not only the via rules of the NGP approach but all subregular alternations in addition, which are seen as the fossil residues of completed phonological change and thus not a matter for synchronic phonology at all (Linell, 1979: 135). Most analysts now distinguish these two types of rule as describing automatic alternations and lexical or MP alternations proper, respectively (Haspelmath, 2002: 181) or principled and casual alternations (Coates, 1999: 67), though there remain minor differences in how particular alternation types are viewed. Linell gives special status to citation forms (cf. MacWhinney's dissertation [1974], reported in MacWhinney, 1978: 82) as providing a base for morphophonemic derivations in a sense compatible with Mańczak's usage of the term 'base' discussed earlier; this base is quite distinct in theoretical terms from the notion underlier, because bases are not formulated with lexical economy in mind, neither is any segment abstraction or form abstraction permitted. Bases for Linell, and Mańczak, are actual grammatical word forms, usually the citation form, of particular lexical items. As such, they are not morphophonemic representations but phonemic ones (or something closely analogous). Dressler (1985) offers a further sophisticated typology of rules that subsumes Linell's proposals.

Phonetic naturalness as a property of some MP rules has often been mentioned above. In generative practice, the most highly valued rules were those that had counterparts in expected historical changes; for instance assimilation of the feature content of one segment to that of some adjacent segment (including what is usually called vowel harmony), epenthesis of consonants to ease the simultaneous switching of several feature values, reduction of the inventory of vowels in unstressed syllables, the breaking up of clusters of consonants and the elimination of hiatus (strings of vowels without intervening consonants), both of which latter types may tend to promote syllable structure consisting of supposedly optimal strings of alternating consonants and vowels (CVCVCV . . .). Some of these processes typically operate also in the distribution of the allophones of phonemes (**Phoneme**), but, by definition, do not result in the alternation of otherwise distinctive sound units. Such processes may also be closely paralleled in the fast speech rules of a language (essentially Dressler's allegro rules [Dressler, 1972], and Linell's articulatory reduction rules [Linell, 1979]).

It is reasonable to see an intimate relationship between all these facts. Fast speech tends to effect changes, not always observed by speakers or hearers, in the form of the words being uttered; the structural units of phonology may thereby come to be pronounced in a greater variety of ways than previously, and may in some phonetic environments come to be pronounced identically to others. At this extreme point in development, alternations will have arisen that are regular and governed by sequence-structure or phonotactic rules. When (1) the processes of analogical leveling get to work on these alternations, when (2) borrowing and lexical creation introduce words of novel pronunciation structure into the language, and when (3) subsequent sound changes () destroy the environments that gave rise to the alternations (making the reasons for their existence opaque), their residue no longer corresponds to the language's previous phonotactics and has come to consist of Linell's MP rules proper, i.e., rules without purely phonetic motivation.

Let us consider some examples of these processes at work, resulting in alternations that are barely identifiable as such without special philological training.

1. Old English /tʃ/ arose from /k/, in morpheme-initial position, only before nonround front vowels as a result of a familiar sort of phonetic change. (It first became a separate phoneme from /k/ in other positions, e.g., after front vowels.) Where front and back vowels once alternated in stems, they could give rise to alternations between /tʃ/and /k/, as in *cēosan* [tʃe:ozan] 'to choose', *(ge)coren* [(jə)korən] 'chosen'. As can be seen, the /tʃ/ occurs in present-day English in an environment where there was an original back vowel (in the perfect participle *chosen*). As a result, any surviving alternations between these phonemes, distinct since late Old English, have lost transparency and synchronic motivation.
2. The borrowing of words from French and other languages with (at the time of the loan) initial /tʃ/ before back vowels accelerated this process (e.g., *choice*, *chock*, *chocolate*), as did the post-Old English creation of new words (such as *chomp*, *chop*, *chortle*).
3. Subsequent sound change in vowels gave rise to words with /tʃ/ followed by a back vowel (as in the cases of *choose* itself, and of *chew*, *choke*, *chalk*). The effect of all these developments was to isolate any surviving alternations between /k/ and /tʃ/, to the extent of making identifying them a matter of historical controversy; as in the case of *cool*, *cold* with /k/ vs. *chill* with /tʃ/, and *cock* with /k/ vs. *chick(en)* with /tʃ/.

The emergence of forms that are inexplicably exceptional to morphophonemic patterns is the most direct testimony to the breakdown of perceived alternation and of alternational regularity.

The relation between final /t/ in certain English verbs and /ʃ/ in their derived abstract nouns (as in *graduate*, *graduation*) is upset by the existence of *equation*, pronounced in RP with /ʒ/. The alternation between /t/ and /ʃ/ is now therefore a morphophonemic rule proper, in Linell's sense.

Facts such as these lead us to the conclusion that there is a one-directional relationship between sound change, automatic (phonetically natural) MP, and lexical (proper) MP (Haspelmath, 2002: 195–199). Regular alternations produced by sound change tend, over the long term, to fossilize into MP that may have exceptions and therefore not be subject to the current phonotactics of the language in question. Such MP does not regeneralize.

Degrees of Regularity or 'Automaticity'

It is possible to set up a typology of MP alternations, in the light of the above comments, based on how 'automatic' their 'operation' is. Most analysts nowadays accept some kind of special status for those alternations that are fully automatic; i.e., in the terms outlined above, which are exceptionless and responsive to aspects of the pronunciation of adjacent units. These are the most purely phonological. The pronunciation triggers may be phonetic, i.e., the pronunciation substance of the adjacent units in question is responsible for the alternation. Cases of this may include vowel harmony, assimilation, and sometimes also epenthesis. Otherwise, the triggers may be phonological in a narrower sense, i.e., it may be the position in the CV structure or skeleton (cf. *see* **Autosegmental Phonology**) that is responsible; we may find end-of-word or end-of-syllable effects, for instance (of which an instance from Russian was given above), or alternations dependent on whether the next segment is a consonant or a vowel (like that which governs whether [r] is pronounced or not in the huge number of words ending in orthographic <r(e)> in many accents of British English: *for*, *dear*, *here*, *visitor*, etc.).

Cross-cutting this classification is the system of possible triggers not having to do with pronunciation, which are therefore not fully automatic in the rather narrow sense defined above. Some MP alternations may be lexically triggered, i.e., occur only in particular items of the vocabulary (like that involving *a/an* in English and that involving the pronunciation of *news* with /s/ instead of /z/ in *newspaper* but not in *newsprint* in the RP accent of English). Some may be triggered only by particular adjacent lexical items, e.g., the so-called contact mutations of certain initial consonants caused in Welsh by the prepositions *i*, *o*. Some may be triggered by the lexical-subclass membership of the affected words; thus, in Welsh, nouns after the article vary their initial consonant in a systematic way only if they fall into the category called 'feminine.' Some may be grammatically triggered. /d/, /t/, and /ɪd/ alternate in a systematic way in English, but only in the regular past tense and the homophonous regular past participle suffix, both spelled <-ed>.

Apophony and MP

Special attention needs to be given to instances of variation in form that do not appear to be cases of MP in the light of the definition given above. It was stated that such alternations as *dust/dusts/dusted/dusting* were not cases of MP, and an explicit warning was given against considering them as such. They are instances of suffixation for the purpose of expressing grammatical distinctions. They do not result in alternating forms of the stem (*dust*) or of the suffixes involved, which are separate units, not alternants of some single one. The same is true for the plural suffixation seen in *station* vs. *stations*. But there are certain English words that show internal modification for the expression of exactly such grammatical categories. The variation seen in the forms *ring/rang/rung* parallels precisely *dust/dusted/dusted*; and *foot/feet* is a precise parallel for *station/stations*. Such element-internal variation is due to the fusion of the lexical items and their grammatical inflection. The fused forms, which cannot be segmented in a way typical of other English morphology, simultaneously realize lexical and grammatical information; this is not true of *dust*, *station*. (It would usually be considered eccentric to say that the verb form *dust* represented the fusion of {dust} and {present tense, non-third-person-singular}, and *station* the fusion of {station} and {singular}, because the grammatical categories mentioned are not overtly marked in other relevant English words.) This internal modification of a stem vowel is called ablaut or apophony. It differs from other cases of MP in that no overt trigger for the variation in form (here, tense/aspect and grammatical number, respectively) is recoverable elsewhere in the linguistic environment in which the word forms are used. It differs, for instance, from synchronic umlaut (a type of vowel harmony), in which some kind of trigger, or rather an indication of the grammatical trigger, is recoverable; in the German singular/plural pair *Gast/Gäste* 'guest(s)' the plurality is additionally marked by a suffix. The terms 'ablaut' and 'umlaut' are often used with a considerable degree of slackness, involving failure to distinguish synchronic criteria from diachronic ones. Diachronically, ablaut was generally used in those instances in which no

historical phonetic motivation for the alternation other than possible tonal differences in the Indo-European protolanguage could be discovered, while umlaut was a phonetically motivated change due to the quality of nearby segments, often regressive assimilation (**Assimilation**). However, from a synchronic point of view, many instances of umlaut are indistinguishable from what might appear to be ablaut. Consider alternations in German such as *Acker/Äcker*. This means 'arable land', singular and plural; the difference has come about in this originally non-alternating word due to analogy with umlauting nouns (i.e., those that show umlaut as a result of sound change in their plural forms), and such nouns are said to have 'joined the umlauting class.' Such word pairs are just like *singen/sangen* 'to sing', non-second person plural present and past tense; but here the difference is due to ablaut. Instances like the former are never called ablaut in the literature about German. Perhaps the word 'ablaut' could usefully be restricted to mean the historical change resulting in this kind of vowel alternation, while 'apophony' could be specialized in a synchronic sense to mean 'internal modification of the stem for exclusively grammatical reasons, and as the sole indication of those reasons.'

This may be the place to discuss further the question of Welsh initial consonant mutation (which is paralleled in the other Celtic languages also). On many occasions, it is a straightforward instance of MP alternation, sensitive to other units in the linguistic environment in which the affected word is found, as illustrated earlier. Sometimes, however, mutation occurs unaccompanied by any overt trigger. Instances of this are vocative usages of nouns, e.g., *gyfaill!* 'friend!', *bawb!* 'everybody!' (whose base forms, in standard descriptions of Welsh, are *cyfaill*, *pawb*); and polar question structures, where the interrogative is signaled (excepting intonation) only by mutation of the sentence-initial verb, as in *allwch chi ddod?* 'can you come?', where the first word is the mutated (in this case consonantless) second-person plural present tense form of *gallu* 'to be able'. Such instances as these are entirely parallel with cases of apophony mentioned above and could reasonably be called consonantal apophony. In the strictest possible interpretation of the term, they are not MP, because the variation in form signals, and is the sole signal of, some difference in grammatical meaning.

Whether one actually regards apophonic phenomena in the general sense sketched here as instances of MP is a matter of definition. They have been excluded here for reasons based on a strict interpretation of the term MP, but it has been considered quite defensible to redraw the boundary to include them, as Dressler (1985: e.g., Sect. 0.3.1) does for at least some instances.

MP in Psycholinguistics

Experimental work (cf. Garman, 1990: Chap. 5) seems to suggest that while morphological patterns are readily perceived, and may in some cases guide the accessing of words in the mental lexicon, and while they may be used analogically in new situations (by children as well as adults), MP patterns are noted much more patchily and are subject to leveling. A famous and much-reported experiment by Jean Berko established that MP rules operating on an exclusively phonological basis were highly likely to be used productively (Berko, 1958, and cf. Derwing, 1980). Her main interest was in children's use of the automatic allomorphy of the regular English plural suffix, which alternates between /z/, /s/, and /ɪz/. At the other end of the plausibility spectrum, a good deal of work has been done to test the psycholinguistic validity of the Great Vowel Shift alternations of English, referred to earlier. When induced to create new lexical items using nonsense stems with, for instance, suffixation by *-ity*, subjects tended strongly to produce words with the expected suffixal structure but without the MP alternation seen in (e.g.) *sane/sanity* (cf. Moskowitz, 1973; Steinberg and Krohn, 1979; Jaeger, 1986; Derwing and Nearey, 1986: 188–196, 205–207). Moskowitz found children able to perform some of the vowel alternations accurately, but they turned out to be being guided by the spelling of the relevant words. Children of around age 7 could stumble, or be manipulated experimentally, into performing any old alternation, suggesting that the use of MP of this type is an acquired skill. Jaeger found no convincing evidence that children acquire MP representations of either a form-abstract or segment-abstract type.

Historically, some leveling has been noted, which tends to reinforce these findings, as in *obese/obesity*, where no alternation of the second vowel is heard in standard dialects of English. There is clear evidence, therefore, that MP alternations are not heeded in a systematic way in acts of lexical creation. As for online processing, either encoding or decoding, there is little to suggest that speakers really do access underlying forms of any great abstraction. Such arguments as were formerly presented in support (e.g., MacKay, 1978) have been criticized as suffering from defective experimental design – they did not show what they purported to show (Henderson, 1985). Indeed, the extent to which speakers process any internal morphological structure of a derivational kind at all in preparing familiar words for spoken as opposed to

written utterance is debatable. Garman acknowledges the 'instability' of morpheme shape – i.e., the very existence of MP – as a problem for psycholinguistics (Garman, 1990: 297). If the paucity of evidence is read at face value, it means that familiar lexical items differing morphophonemically from each other must be stored in a phonological sense independently of each other, not derived from phonologically unitary morphological primitives online. This view seems to be contradicted in an experiment by Stanners *et al.* (1979). They set up a lexical priming task (i.e., one where the investigators let subjects hear a word that is supposedly relevant in some way to the one they wish the subject to say before he or she says it, with a view to influencing what is actually said). Their subjects' responses were to some extent (though not remarkably) inhibited (i.e., slowed down) by being offered primers requiring the desired response words to undergo phonological adjustments of the type (P) *describe* → (R) *descriptive*. As revealed by such apparent evidence of a certain processing cost, therefore, the connections between the words, while being essentially semantic and/or grammatical, are also, even if to a lesser degree, phonological. That allows the possibility that speakers perform some online phonological derivation. However, evidence interpretable as showing the opposite was presented by Fowler *et al.* (1985): that priming by words inflectionally (i.e., regularly) and derivationally (i.e., potentially with phonological irregularity) related to the target word was equally effective. This whole difficult area is reviewed by Marslen-Wilson *et al.* (1994: especially 30–31), who offer a sophisticated model of the phonological level of lexical representation allowing some degree of phonologically abstract representation. In recent work, Bybee (2001: especially Chaps. 3, 5) makes the radical but well-motivated proposal that the entities that are stored in the mind are extrapolations from tokens of words actually experienced in usage, and that connections between related but different forms, while undoubtedly real, are not reified as units of an abstract representational level; that is, morphophonemes as such do not exist, even if recurrent partial resemblances between morphemes (or in her model, words) do.

It is possible, indeed highly likely, that the connections between separate but formally related lexical entries may sometimes come to receive a phonological interpretation, however; some principles are quite well established, such as 'one meaning, one form,' which is to be understood here as pressure for historically related words of similar meaning to gain, or regain, similar pronunciation (analogical leveling), and the somewhat grossly misnamed 'folk etymology,' which has to do with similar pressures divorced from the need for a shared origin, as when the English word *female* acquired its present shape through historically unwarranted association with the semantically related (antonymous) word *male*. But these pressures are emphatically not about shared underliers related to actual pronounced forms by a battery of successively transformed states of the human 'phonology machine.'

There is a very important issue which, as a psychological issue, is only partially made explicit and addressed in the pages above. This is the question of storage vs. computation (processing). For a given set of alternants, are all stored in the mental lexicon (and, if so, are they stored with equal status)? Or is one of the set stored and the others derived from it as required during processing? Or is some surrogate for the whole set stored and all actual alternants derived from that? Our current state of knowledge allows us to come to provisional but fairly well supported conclusions on this question. The account given below is based mainly on the vast amount of evidence collected and presented by Dressler (1985), but does not agree in every detail. He takes into account child language acquisition, language processing, and language pathology (aphasiological) data.

1. For suppletive alternants, it is clear that all must be stored, though not necessarily as equal partners; for essentially semantic and/or grammatical reasons, one form may be basic and the other(s) less central, in some sense, in the word's entry in the mental lexicon.
2. For those alternations that are described here as 'purely phonological,' i.e., phonetically natural and exceptionless, it is reasonable to postulate the storage of a single alternant, converted by a phonological rule to produce others during the act of speaking. This seems to be supported by the preservation of a general suffixal alternation pattern in some production errors involving lexical transposition (Garrett, 1980; Henderson, 1985: 28). There are grounds for supposing, however, that in cases of potential communication difficulty (e.g., to avoid ambiguity or the appearance of facetiousness) the operation of such automatic rules may be suppressed (cf. e.g., Gussmann, 1979: 102, who mentions that in Polish *pocztowy kod* 'postcode' may be avoided because the second word is pronounced [kɔt], making the expression homophonous with 'postcat').
3. For other alternations, the evidence is less clear-cut. Those that describe the behavior of relatively few, often irregularly or unnaturally alternating, words may be considered as suppletive. New alternants created on the basis of such older sets may be

considered as analogical (cf. MacWhinney, 1978). Essentially regular alternations that are not 'purely phonological' seem able to tolerate exceptions. A cline of productivity in such alternations may be seen, therefore, which suggests that no single psychological mechanism may account for them. As Bauer (1983: 130) puts it: "... there does not seem to be any principled way to decide under what conditions two surface phonetic strings [i.e., alternants, R. C.] should be derived from the same underlying morpheme, that is, when the rules of the phonology should predict a given alternation, and when they should not, and consequently, when words should be considered as being linked by a process of word-formation [i.e., morphology, R. C.]." Dressler is prepared to allow a highly redundant model involving both the storage of all alternants in these cases and the existence of rules relating them (cf. also in relation to the production of spoken word forms Anshen and Aronoff, 1988), and a two-level model of phonological lexical relatedness, i.e., one with differing levels of permitted phonological abstraction, is proposed by Marslen-Wilson *et al.* (1994). It would be satisfying to envisage these rules as being differentially grasped by different speakers, i.e., to be a function of their own individual insight and/or explicit teaching, and therefore to be used to different degrees in structuring their individual mental lexicons and in governing the patterns of alternation in their creation of new words. It would not follow from such a view that these rules are used in routinized online processing of words that are already part of the lexicon. Whether they are or not is in principle an empirical matter, but in practice very difficult to investigate.

A problem that has not so far been teased out, and to which there is no clear solution, has to do with whether MP alternations of any sort have equal significance in both directions of psycholinguistic processing: production (encoding) and reception (decoding) of utterances. We might envisage that an ability to reverse the effect of MP rules could be of assistance in decoding the morphology, and hence the meaning, of unknown or partly undecoded words. This view is enshrined in the system called upside-down phonology proposed by Leben and Robinson (1977). MP would in this system be a court of appeal that was more or less consciously accessible in cases of uncertainty. For instance, in hearing the new word *conflagrate* in adverse conversational conditions, an English user knowing the word *conflagration* might be able to arrive at an identification partly on the basis of knowledge of the relation between /ʃ/ in nouns and /t/ in related verbs. Maybe MP, viewed as a set of redundancy rules over the existing lexicon of a language, could constrain the encoding of unfamiliar material in the same way.

Conclusion and State of the Art

MP alternations seem best summed up as statements about regularities, subregularities, or irregularities of lexical relations between phonemes across the vocabulary of particular languages (or better, lects of any description) discerned by linguists, but not attended to in any systematic way by naïve speakers. Speakers may internalize them in a subconscious way, of course, and normally do so during routine first-language learning. They may become adept at using MP alternations and apophonic ones in practical ways as a result of instruction or insight, for instance in the creation of new vocabulary or in exploiting such alternations to make form-sensitive jokes (e.g., the often-observed *Wittgensteinian* with the vowel in the third syllable pronounced /ɪ/; *snuck*, *thunk*, *succame* for *sneaked*, *thought*, *succumbed* in English – institutionalized to different degrees in the vocabularies of different speakers).

The study of MP in its familiar form has become sidelined since the mid-1990s because of the development of Optimality Theory (OT) in phonology (**Pragmatics: Optimality Theory**) in which rules as previously conceived, and the unique underlying forms that license them, have no place. The protagonists of OT (Prince and Smolensky, 1993) noted that rules were often set about with constraints, sometimes *ad hoc*, on their operation, and have reconceptualized phonological systems as systems describing sets of phonological forms that satisfied constraints, rather than being derived from anything that could be reified such as a systematic phonemic (level of) representation. The work by Bybee referred to above has also bypassed MP as usually conceived.

Morphopragmatics

L Merlini Barbaresi, University of Pisa, Pisa, Italy

© 2006 Elsevier Ltd. All rights reserved.

Definition

Morphopragmatics is a subdiscipline integrating morphology and pragmatics. It describes grammatical morphological phenomena (within both word formation and inflection), capable of systematically contributing autonomous pragmatic meanings to discourse. Morphopragmatics is definable as the set of general pragmatic meanings/effects obtained by morphological rules. The privileged objects of a morphopragmatic description are evaluative suffixes, such as diminutives, as in Portuguese *adeuz-inho,* Spanish *hasta lueg-ito* 'good-bye-DIM,' augmentatives, as in Spanish *cabez-ota* 'big head'; Portuguese *animal-aço* 'huge animal,' elatives, as in Italian *fort-issimo*, 'very strong,' but also reduplicatives, as in Italian (*occhi*) *neri neri* 'very dark (eyes),' excessives, as in German *das Aller-schlecht-este* EXC-bad-SUPERL 'the very worst,' and, within inflection, personal pronouns of address and Japanese honorifics.

The model fills in a gap concerning meanings not systematically dealt with by linguists, although influential in interactive discourse. Evaluative/alterative affixes, the major representatives of the central category investigated by the model, are characterized by semantic elusiveness, i.e., they exhibit no stable semantic value in terms of either denotations or connotations, and their meaning contributions to the speech event are better described within pragmatics, e.g., in terms of their dependence on speech situations, speech acts, attitudes of interactants. Due to lack of semantic stability, their meanings have been granted sporadic and impressionistic descriptions by morphologists. Pragmaticists, on the other hand, have overlooked morphopragmatic meanings as these are often overridden by the general pragmatic impact of the word meanings or, even, of the syntactic construction, which is perceived as more influential in terms of pragmatic constraints. For example, in a request such as *wouldn't you read this book-let* (a thick volume!) *for me?*, the diminutive *book-let* is pragmatically intended to downgrade the load of the request, but the *wouldn't*-construction is capable of the same effect and may darken the pragmatic contribution of the suffix *-let*. Morphopragmatics is intended to shed light on cases of exclusive relationships between morphology and pragmatics. It is a framework for describing cases of grammaticalized (i.e., morphologized) pragmatics, i.e., pragmatic effects produced by grammatical operations. The model marginalizes extra-grammatical phenomena, as in, for example, English reduplicatives (*teeny-weeny*) or slangy formations (*lanky* ← 'Lancashire'), although these obtain similar discursive effects because they belong to a heterogeneous group of word-forms admitting irregularities in their coining.

The Theory

The theory was pioneered by Wolfgang U. Dressler and Lavinia Merlini Barbarese in successive steps (Dressler and Merlini Barbarese 1986, 1987, 1991), and expanded into a fully fledged model in 1994. It started with the observation that some still productive elements, Italian interfixes such as *-ic-, -ol-*. and *-e/ar-*, placed before evaluative suffixes (as in *brutt-ar-ella* 'ugly-INT-DIM' 'not exactly nice'), retained some pragmatic effects as a remnant of their former status as suffixes, although, synchronically, they were semantically empty, i.e., denotationally meaningless. The investigation of such effects prompted the authors' interest toward the entire paradigm of evaluative suffixes. Predictably, meaningful suffixes also had a privileged and autonomous relationship with pragmatics. It is in this area that morphopragmatic studies achieved their most fruitful results. Other applications are Dressler and Kiefer (1990) on German and Hungarian excessives, Kilani-Schoch and Dressler (1999) on French *-o* suffix, Crocco Galéas (1992) on Italian ethnics, Merlini Barbaresi (1999) on English -y/ie suffix, and more recently Cantero, 2003 on Spanish phenomena.

Morphopragmatics is parallel to other well-established subdisciplines, such as morphosemantics, lexical semantics of morphology, lexical pragmatics of morphology, and pragmatics of syntactic patterns and textual strategies, but it is to be carefully distinguished from them:

- Morphosemantics studies the semantic meanings of morphological rules, i.e., the regular denotational and connotational modifications obtained by derivational or inflectional rules. Within a morphosemantic investigation, pragmatic variables connected with speech situations become irrelevant. Reference to a pure denotational meaning of smallness added by a diminutive suffix, as in *room-ette*, belongs here.
- Lexical semantics of morphology deals with the denotational and connotational meanings of single, morphologically complex, words, as lexicalized *star-let*.
- Lexical pragmatics deals with the pragmatic meanings idiosyncratically conveyed by single complex

words, such as lexicalized *bunn-y* 'rabbit,' selecting a child environment and obtaining a meaning of endearment.

- Syntactic patterns and textual strategies may convey pragmatic meanings of their own and interfere with those obtained by single constituents of the text.
- Morphopragmatics deals, instead, with pragmatic meanings that can be regularly obtained through the sole application of morphological rules, given certain sets of contextual conditions. The morphological operation may be totally responsible for the added utterance meanings, with the wordbase being either neutral (*dogg-y*) or contributory (*dear-ie*, Italian *piccol-ino* 'small-DIM') or even contrary (Italian *gross-ino* 'big-DIM') to the effect pursued.

The Tenets of the Theory

The theory relies on the assumption that pragmatic meanings are not completely derivable from semantic meanings with the help of general pragmatic principles; it favors the claim that a morphopragmatically relevant rule possesses some nonsemantic, autonomous pragmatic feature in its meaning description. In the case of Italian diminutives, for example, the pragmatic effects they obtain cannot be derived from a semantic meaning [small] with its allosemes [unimportant] and [young]. They are based on an autonomous pragmatic feature [fictive], and on a derived, more specific character [nonserious]. Evidence of that is the fact that many of such pragmatic effects can also be obtained by augmentatives, which share with diminutives the pragmatic feature [fictive], but certainly not the semantic meaning [small]. In Italian, saying to somebody:

(1) mangi come un maial-ino
you eat like a pig-DIM
'you eat like a little piggy'

would not sound dissimilar from:

(2) mangi come un maial-one
you eat like a pig-AUGM
'you eat like some huge pig'

In both cases, the suffix is capable of hedging the critical remark, i.e., of downgrading the illocutionary force of the evaluative assertion, via a playful character added. Compare with a nonsuffixed version:

(3) Mangi come un maiale
'you eat like a pig'

which is insulting and likely to cause an angry retort by the addressee.

The playful character, on the other hand, cannot be viewed as a stable connotation of the two suffixes, because, with a change of context (e.g., a sarcastic approach), the same suffixes may turn their meanings into aggravating unpleasantness. See:

(4) Italian: vuoi tener fuori le tue man-ine/one dai miei affari, per favore?
will you keep out the your hand-DIM/AUG-PL from the my business-PL, please?
'why don't you mind your own bloody business'

Fictiveness is conceptualized as a departure from conventionally accepted standards of meaning; it generates a frame of personalized values where such standards glide according to the speaker's evaluation. Fictiveness creates an area of fuzziness, which, in interactional discourse, needs explanations and allows negotiation, as in:

(5) Italian: il tuo articolo è un po' cort-ino
the your article is a little short-DIM
'your article is a bit short, I'm afraid'

A likely rebuttal could be:

(6) che intendi per cort-ino?
what do you mean by short-DIM?

The use of the un-affixed base *corto* (as in *l'articolo è corto* 'the article is short'), by contrast, would activate conventional standards and would not allow meaning negotiation; it might at most trigger a discussion on what is 'short' for an article, due to the meaning relativity of dimensional adjectives.

In Italian, but also in other languages, such as Spanish, Portuguese, German, English, Dutch, Polish, Russian, and others, a diminutive formation produces modifications that may be at the same time relevant for morphosemantics, i.e., denotational diminution and positive or negative connotations, and for morphopragmatics, i.e., fictiveness and its derived character [nonserious], capable of constraining the type of speech situations and of downgrading the strength of the illocutionary force of the entire utterance. So, in the Italian example above, the diminutive formation *un po' cort-ino* 'a bit short-DIM', besides conveying a meaning of semantic diminution, by virtue of its fictive and nonserious character, suits a case of nonofficial evaluation, indicates the speaker's lower responsibility in uttering it and obtains mitigation of the critical remark.

Morphopragmatic effects may even be independent of the denotative meaning of smallness and of connotational meanings of positivity (pleasantness, coziness, etc.), or negativity (meanness, meagerness), or emotionality (endearment, tenderness). Cases are conceivable in which none of these meanings is

actually activated and still morphopragmatic effects obtain, as in:

(7) Italian: ho bisogno di una sua firm-etta qui, per favore
I have need of a your signature-DIM here, please
'well, now, could you just sign here, please?'

where the meaning [small] of the suffix in *firm-etta* is suspended and superseded by its feature [nonserious], which lowers the speaker's responsibility for the face-threatening directive speech act and obtains a downgrading of the deontic imposition of the request and of the requestee's liability in case of noncompliance.

A fictive character is recognizable also in other morphological rules, as, for example, in German and Hungarian excessives. From a semantic viewpoint, excessives are not different from superlatives: like these, they indicate the highest possible degree of a value along a scale, but excessives obtain a fictive upgrading of this extreme, which can be exploited, for example, in paradoxical or sarcastic hyperboles, as in:

(8) German: aber das Aller-schoen-ste kommt erst jetzt
but the EXC-beautiful-SUPERL comes only now
'but the most beautiful of all is about to come up now'

where 'beautiful' is used sarcastically of something unpleasant.

The model also concerns morphopragmatics in inflection, as, for example, Japanese honorifics, particularly the suffix *–masu*, which indexes social and psychological distance in conversation. The honorific system is a matter of morphopragmatics because its sociopragmatic meaning is biuniquely expressed by such suffixes.

New, promising areas of morphopragmatic studies have recently opened up, for example in language acquisition (Dressler, 1997).

Factors Favoring Morphopragmatic Meanings

Child-centered speech situations and the emotionality involved, the ludic character of playfulness among intimates, familiarity and informality in general, sympathy and empathy, but also understatement, euphemism, false modesty, irony and sarcasm, are all factors favoring morphopragmatic meanings of diminutive formations and other morphological rules. In a child-centered speech situation, the feature [nonserious] is constitutive and triggers diminutive formations. Examples are:

(9) who's my lovely little girl-ie?
German: wer komm-erl-t denn da?
who come-DIM-s PART here
'what cute boy is coming here?'

involving emotions and signaling intimate relations between mother and child. The other factors, such as irony, understatement, etc., are regulative. See below:

(10) Italian: un tantino anziano per lei, no? (irony)
a bit-DIM old for her, no?
'a shade old for her, eh?'

(11) Italian: io facevo un ragionamento un po' divers-ino (understatement: downgrading speaker's responsibility; said by a student to a professor)
I made a reasoning a bit different-DIM
'I was approaching the matter slightly differently'

Emotive factors are not primarily connected with diminutive formations, as can be seen from the last example. Constitutive and regulative factors combine in determining the application of the rule, which is also dependent on whether the utterance contains a suitable base for the suffix. Whatever the word chosen as a base ('landing site'), the effects clearly extend to the entire utterance.

Morphotactics

J Hay, University of Canterbury, Christchurch, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Tactics refers to the ordering of elements at any level of linguistic structure, and the rules that govern this ordering. Morphotactics, then, deals with the possible sequencing of morphemes within words. Researchers studying morphotactics are concerned with the question of why some combinations of morphemes are completely acceptable (e.g., *atomlessness, atomicity*) and others are unacceptable (*atomlessity, atomnessic*). More recently, attention also has turned toward accounting for degrees of acceptability.

A common observation regarding the ordering of affixes concerns the relative ordering of inflectional and derivational affixes. Derivational affixes are affixes which create new words (e.g., *-ity*, *-ness*), as opposed to inflectional affixes (such as plurals, and tense markers) that simply add grammatical information to existing words. In general, where a language has both inflection and derivation, derivational affixes are positioned between the stem and the inflection (Greenberg, 1963). That is, inflections can be added to words that contain derivational morphemes, but derivational morphemes cannot be added to words that contain inflectional affixes.

Inflectional affixes themselves seem to show hierarchies of proximity to the stem (Greenberg, 1963). Bybee (1985) investigated the ordering of verbal inflectional affixes across 50 languages and found a hierarchical ordering of aspect, tense, mood, and person, where aspect tends to appear closest to the stem, and person tends to occur furthest from the stem. This suggests that the ordering of inflectional affixes is governed by a relevance hierarchy, such that the more relevant the meaning of the inflectional morpheme is to the meaning of the verb, the closer it will appear to the verb stem.

Rice (2000) also finds a role for semantic factors in her survey of the highly complex verbal morphology in Athabascan languages. These languages display a systematic relationship between morpheme ordering and scope. In Athabascan languages, the ordering of elements is fixed whenever the scopal relation between them is fixed. This finding is consistent with the more general observation that meanings that are closer to the verb will appear closer to the verb. However, in Athabascan languages, this extends to a wide range of affixes, including derivational affixes. The degree to which this account can be extended to other languages has yet to be explored.

Although semantics certainly plays a role in the ordering of derivational affixes, the literature on derivational affixes has tended to focus on other issues. A particular focus has been the degree to which it is desirable to distinguish between different 'classes' of derivational affixes in order to explain their ordering. This debate has been waged largely on the turf of English derivation. The question of the restrictions on ordering among derivational affixes in English is one of the most debated problems of English morphology. Of the many potential combinations of different affixes, only a very small number actually occur. The challenge is to provide an account that eliminates all of the nonoccurring combinations, but allows those combinations that are attested.

It is well established that, phonologically, English has two types of derivational affixes – those that affect the phonology of the base to which they attach (such as *-ity*, and *-ic*), and those that do not (*-less*, *-hood*)

Tactics refers to the ordering of elements at any level of linguistic structure, and the rules that govern this ordering. Morphotactics, then, deals with the possible sequencing of morphemes within words. Researchers studying morphotactics are concerned with the question of why some combinations of morphemes are completely acceptable (e.g., *atomlessness, atomicity*) and others are unacceptable (*atomlessity, atomnessic*). More recently, attention also has turned toward accounting for degrees of acceptability.

A common observation regarding the ordering of affixes concerns the relative ordering of inflectional and derivational affixes. Derivational affixes are affixes which create new words (e.g., *-ity*, *-ness*), as opposed to inflectional affixes (such as plurals, and tense markers) that simply add grammatical information to existing words. In general, where a language has both inflection and derivation, derivational affixes are positioned between the stem and the inflection (Greenberg, 1963). That is, inflections can be added to words that contain derivational morphemes, but derivational morphemes cannot be added to words that contain inflectional affixes.

Inflectional affixes themselves seem to show hierarchies of proximity to the stem (Greenberg, 1963). Bybee (1985) investigated the ordering of verbal inflectional affixes across 50 languages and found a hierarchical ordering of aspect, tense, mood, and person, where aspect tends to appear closest to the stem, and person tends to occur furthest from the stem. This suggests that the ordering of inflectional affixes is governed by a relevance hierarchy, such that the more relevant the meaning of the inflectional morpheme is to the meaning of the verb, the closer it will appear to the verb stem.

Rice (2000) also finds a role for semantic factors in her survey of the highly complex verbal morphology in Athabascan languages. These languages display a systematic relationship between morpheme ordering and scope. In Athabascan languages, the ordering of elements is fixed whenever the scopal relation between them is fixed. This finding is consistent with the more general observation that meanings that are closer to the verb will appear closer to the verb. However, in Athabascan languages, this extends to a wide range of affixes, including derivational affixes. The degree to which this account can be extended to other languages has yet to be explored.

Although semantics certainly plays a role in the ordering of derivational affixes, the literature on derivational affixes has tended to focus on other issues. A particular focus has been the degree to which it is desirable to distinguish between different 'classes' of derivational affixes in order to explain their ordering. This debate has been waged largely on the turf of English derivation. The question of the restrictions on ordering among derivational affixes in English is one of the most debated problems of English morphology. Of the many potential combinations of different affixes, only a very small number actually occur. The challenge is to provide an account that eliminates all of the nonoccurring combinations, but allows those combinations that are attested.

It is well established that, phonologically, English has two types of derivational affixes – those that affect the phonology of the base to which they attach (such as *-ity*, and *-ic*), and those that do not (*-less*, *-hood*)

(Bloomfield, 1933; Newman, 1946). Chomsky and Halle (1968) label the former nonneutral affixes, which create a weak boundary (+), and the latter neutral affixes, which create a strong boundary (#).

Siegel (1974) proposed that this phonological division correlates with a morphological division in terms of the potential ordering of the morphemes involved. The basic claim of Siegel's Affix-Ordering Generalization is that affixation occurs at two different strata – commonly known as level 1 and level 2. Level 1 affixation occurs prior to level 2 affixation, and so, as a consequence, no level 1 affix can attach outside of any level 2 affix.

Many attempts to account for apparent restrictions on affix ordering in English have invoked some form of the affix-ordering generalization. The affix-ordering generalization also is known as the level-ordering hypothesis, and forms a part of most models of lexical phonology. Some common English suffixes and prefixes and their proposed strata membership are as follows:

(1) Level I suffixes: +ion, +ity, +y, +al, +ic, +ate, +ous, +ive, +able, +ize
Level I prefixes: re+, con+, de+, sub+, pre+, in+, en+, be+
Level II suffixes: #ness, #less, #hood, #ful, #ly, #y, #like, #ist, #able, #ize
Level II prefixes: re#, sub#, un#, non#, de#, semi#, anti#
(Spencer, 1991: 79)

As noted, level 1 affixes may cause various phonological changes in the stems to which they attach, whereas level 2 affixes do not. The affixes belonging to each level share various additional properties. For example, level 1 affixes tend to be Latinate, whereas level 2 affixes tend to be Germanic. In addition, level 1 affixes can attach to bound roots, and tend to be phonologically and semantically less transparent than level 2 affixes. Crucially, in terms of accounting for morphotactics, level 1 affixes may not attach outside level 2 affixes. Thus, the affix-ordering generalization can account for the acceptability of *atomlessness* and *atomicity*, and correctly rules out *atomlessity* and *atomnessic,* both of which contain a level 1 affix attached after a level 2 affix.

Authors who have utilized stratum-based models along these general lines include Siegel (1974), Allen (1978), Selkirk (1982), Kiparsky (1982), Mohanan (1986), and Giegerich (1999). Most authors also incorporate compounding and inflection into their level-ordered approaches, although there is variation in exactly where this is done, and how many levels result. Level-ordered approaches have achieved explanatory power in languages other than English, although the number of proposed levels varies, as do the criteria on which the levels are differentiated. Booij (2001) identifies the following languages as having received level-ordered treatments of morphotactics: Dutch, Malayam, Dakota, Mandarin, Icelandic, German, Igbo, Italian, Basque, and Turkish.

Several different types of objections to the affix-ordering generalization have been made. Although level ordering appears to rule out a large number of unattested affix combinations, it does not make any predictions about possible and impossible combinations within a given level. In fact, it predicts that all combinations of affixes within a level should theoretically be possible.

Fabb (1988) investigates the possible combinations of 43 English suffixes. He finds that syntactic restrictions, together with level-ordering constraints, limit the possible combinations of these suffixes to 459. However, of these 459, only 50 are actually attested. Thus, the power of the level-ordering hypothesis is not as strong as first appeared – it does rule out some unattested combinations of affixes, but it leaves many more unexplained. Fabb argues that English morphotactics solely result from the selectional restrictions held by individual affixes. That is, each affix has certain phonological, semantic, and syntactic restrictions, which limit the type of base it can attach to. One of the most widespread restrictions is a restriction against attaching to an already suffixed word. Because such restrictions are necessary to account for cooccurrence patterns within each level, then they also are likely to operate across levels. This renders the levels themselves redundant, at least in terms of explaining affix ordering.

A related approach (Plag, 1996) ascribes the morphotactic patterns to selectional restrictions but positions the restrictions with the base, rather than the affix. In a base-driven approach, each stem or affix contains specifications restricting what can attach to it. This differs from an affix-driven approach, in which each affix contains specifications restricting what it can attach to.

Hay (2002, 2003) proposes an account of ordering that is based on parsability: *complexity-based ordering*. Complexity-based ordering claims that many constraints on ordering are a result of general language-processing mechanisms. Some affixes are very easy to parse, and words containing these affixes are likely to be accessed via their parts in speech perception. Other affixes are much less parsable, and words containing them are likely to be accessed whole in speech perception. Complexity-based ordering maintains that less parsable affixes, cannot attach to more parsable affixes.

This account captures one of the primary insights of the affix-ordering generalization. Affixes create

different boundary strengths, and there is some relationship between boundary strength and ordering. However, this insight is extended by considering boundary strength to be gradient, and a function of decomposability in speech perception. The overall prediction is that the less phonologically segmentable, the less transparent, the less frequent, and the less productive an affix is, the more resistant it will be to attaching to already affixed words. Hay and Plag (2004) investigate a set of English suffixes, and demonstrate that they can be ordered on a hierarchy of boundary strength, with suffixes with weaker boundaries being located closer to the base, and with suffixes with stronger boundaries being located further away from the base. Although this new approach looks promising, it remains to be tested in other languages, and with further empirical data.

Morpurgo Davies, Anna (b. 1937)

J T Katz, Princeton University, Princeton, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Anna Elbina Laura Margherita Morpurgo Davies, Diebold Professor of Comparative Philology, Emerita, at the University of Oxford, is the most distinguished living historical linguist in the United Kingdom. An Italian national from a prominent academic family, she was born in Milan on June 21, 1937 but has spent nearly her entire career at Oxford, where she was for seven years University Lecturer in Comparative Philology before being named in 1971 to what would come to be called the Diebold Professorship, a position she held for a record 33 years. The recipient of numerous honors from universities and academies the world over, she was awarded an Honorary DBE in 2000 for services to philology and was presented with a festschrift with 42 contributions on the occasion of her retirement in 2004.

The hallmark of Morpurgo Davies's scholarship is the careful analysis of large bodies of often difficult data. She is best known for her pioneering work in three quite distinct areas: the interpretation of Ancient Greek dialects, particularly Mycenaean (Linear B), but also Arcado-Cyprian, Thessalian, and others; the decipherment and analysis of the Anatolian language Hieroglyphic Luvian; and the elucidation of the history of linguistics, especially in the 19th century. In addition to numerous reviews and encyclopedia entries, Morpurgo Davies has written nearly 70 articles in major academic venues and is the author of three books (one in each of the subjects just mentioned) and the co-editor of two more. A focus

Anna Elbina Laura Margherita Morpurgo Davies, Diebold Professor of Comparative Philology, Emerita, at the University of Oxford, is the most distinguished living historical linguist in the United Kingdom. An Italian national from a prominent academic family, she was born in Milan on June 21, 1937 but has spent nearly her entire career at Oxford, where she was for seven years University Lecturer in Comparative Philology before being named in 1971 to what would come to be called the Diebold Professorship, a position she held for a record 33 years. The recipient of numerous honors from universities and academies the world over, she was awarded an Honorary DBE in 2000 for services to philology and was presented with a festschrift with 42 contributions on the occasion of her retirement in 2004.

The hallmark of Morpurgo Davies's scholarship is the careful analysis of large bodies of often difficult data. She is best known for her pioneering work in three quite distinct areas: the interpretation of Ancient Greek dialects, particularly Mycenaean (Linear B), but also Arcado-Cyprian, Thessalian, and others; the decipherment and analysis of the Anatolian language Hieroglyphic Luvian; and the elucidation of the history of linguistics, especially in the 19th century. In addition to numerous reviews and encyclopedia entries, Morpurgo Davies has written nearly 70 articles in major academic venues and is the author of three books (one in each of the subjects just mentioned) and the co-editor of two more. A focus

of her current research is Greek onomastics, the subject of her 2000 Sather Lectures at the University of California, Berkeley, the most prestigious lecture series in the field of Classics.

Morpurgo Davies's first book, *Mycenaeae Graecitatis lexicon* (1963), was the first dictionary of Mycenaean, the oldest Greek dialect we possess and one that had been deciphered only a decade earlier. She has solved many lexical, phonological, and especially morphological problems in Greek dialectology and has done more than anyone else in the English-speaking world to promote the study of Classical languages and texts from a sociolinguistic perspective.

In 1973, Morpurgo Davies published, together with J. D. Hawkins and Günter Neumann, *Hittite hieroglyphs and Luwian: new evidence for the connection*, a work that established the readings of a number of critical Luvian hieroglyphs. The discoveries reported there and in subsequent articles, many with Hawkins as co-author, have laid the foundation for the serious study of Hieroglyphic Luvian, the only Indo-European language written in an indubitably indigenous system.

Finally, in a series of papers and a 1998 book, *Nineteenth-century linguistics* (written in English but published earlier in Italian), Morpurgo Davies has chronicled the exciting and often choppy development of linguistic ideas in Europe from, roughly speaking, Franz Bopp to Karl Brugmann.

Morris, Charles (1901–1979)

M Net, Bucharest, Romania

© 2006 Elsevier Ltd. All rights reserved.

Charles William Morris was born in Denver, Colorado on May 23, 1901 and died in Gainesville, Florida, on January 15, 1979.

He studied at the University of Chicago, and received his Ph.D. in philosophy in 1925. His academic career included the jobs of instructor at the Rice Institute (1925–1931), Associate Professor (1931–1947) and lecturer (1948–1958) at the University of Chicago, and Research Professor at the University of Florida. He also taught at Harvard and at the University of Texas.

In 1934, Morris edited the collection of lectures *Mind, self, and society* by his former Professor George Herbert Mead.

Morris was interested in logical positivism, and in scientific empiricism as promoted by the Vienna Circle. He dealt in formal logic (along the line inaugurated by Rudolph Carnap), behavioral psychology, and language philosophy. He participated in the international congresses of the philosophy of science (Prague 1934, Paris 1935).

From the beginning of the 1930s, Morris gave the very first course in semiotics (so labeled). He thought a close interdependence existed between science and semiotics. Consequently, in his first major work, *Foundations to a theory of signs* (1938), Morris claims that science is "at once a language, a knowledge of objects, and a type of activity." The *Foundations* were originally intended as the first volume of an *International encyclopedia of unified science* (a project promoted by Neurath and Carnap). The basic idea in this work is the tripartition of semiotics into syntactics, semantics, and pragmatics. This distinction was also adopted in linguistics. Pragmatics, as studied by contemporary linguistics, originates in Morris' idea of a branch of semiotics concerned with "the relations of signs to their interpreters."

His next major work was *Sign, language, and behavior* (1946), which developed along the same lines.

In 1964, he published *Signification and significs*; the basic idea thereof is that semiotics studies "what signs signify to certain persons, how signs are

Morris, Charles (1901–1979)

M Net, Bucharest, Romania

© 2006 Elsevier Ltd. All rights reserved.

Charles William Morris was born in Denver, Colorado on May 23, 1901 and died in Gainesville, Florida, on January 15, 1979.

He studied at the University of Chicago, and received his Ph.D. in philosophy in 1925. His academic career included the jobs of instructor at the Rice Institute (1925–1931), Associate Professor (1931–1947) and lecturer (1948–1958) at the University of Chicago, and Research Professor at the University of Florida. He also taught at Harvard and at the University of Texas.

In 1934, Morris edited the collection of lectures *Mind, self, and society* by his former Professor George Herbert Mead.

Morris was interested in logical positivism, and in scientific empiricism as promoted by the Vienna Circle. He dealt in formal logic (along the line inaugurated by Rudolph Carnap), behavioral psychology, and language philosophy. He participated in the international congresses of the philosophy of science (Prague 1934, Paris 1935).

From the beginning of the 1930s, Morris gave the very first course in semiotics (so labeled). He thought a close interdependence existed between science and semiotics. Consequently, in his first major work, *Foundations to a theory of signs* (1938), Morris claims that science is "at once a language, a knowledge of objects, and a type of activity." The *Foundations* were originally intended as the first volume of an *International encyclopedia of unified science* (a project promoted by Neurath and Carnap). The basic idea in this work is the tripartition of semiotics into syntactics, semantics, and pragmatics. This distinction was also adopted in linguistics. Pragmatics, as studied by contemporary linguistics, originates in Morris' idea of a branch of semiotics concerned with "the relations of signs to their interpreters."

His next major work was *Sign, language, and behavior* (1946), which developed along the same lines.

In 1964, he published *Signification and significs*; the basic idea thereof is that semiotics studies "what signs signify to certain persons, how signs are

considered in a specific language, the origin, uses, and effects of specific signs."

Morris organized the 5th and 6th International Congress for the Unity of Science. He was Fellow of the American Academy of Arts and Sciences, and President of the Western Division of the American Philosophical Association (1936–1937).

In 1977, *Ars Semeiotica. International Journal of American Semiotics* was launched at the University of Colorado, under the patronage of Charles W. Morris.

Morris, Charles: Theory of the Sign

W C Watt, University of California, Irvine, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Charles W. Morris (1901–1979), who spent most of his scholarly life at the University of Chicago, influenced both semiotics and linguistics from the 1930s through the 1950s. In semiotics he formed a bridge between Charles S. Peirce's abstractly tenebrous works and the foundation in 1962 of the modern discipline, with its growing scientific emphases; in linguistics he promoted pragmatics, the study of language as people actually use it. To both disciplines he brought the belief that the study of signs would advance the unity of science; this faith, which his best-known student later conceded was largely restricted to "programmatic announcements" (Sebeok, 1979: 65), was advanced in his 'Foundations of the theory of signs' (1938) – a chapter in a volume entitled *Foundations of the unity of science: toward an international encyclopedia of unified science* – and in later works such as *Signs, language, and behavior* (1955) and *Signification and significance* (1964). The 'unity of science' now seems a rather quixotic endeavor, but Morris's ecumenical influence can still be discerned wherever biologists characterize how other creatures (and even plants) signal to one another (e.g., Frings and Frings, 1964; Sebeok, 1968; Krampen, 1981) and in the semiotic notion that the means by which biotic sign users send and receive signs is a cardinal aspect of signs themselves (for Morris, their 'sign-vehicles'). In this respect Morris argued for charging Peirce's notion of the interpretant, an abstraction, with physical reality, thus beneficially altering the modern notion of semiosis, the transmission of signification, so that it acknowledged that sign-vehicles are affected by brains and bodies. This view led ultimately to cognitive semiotics and an examination of how signs owe their forms to their senders' and receivers' (neuro-)anatomies (Watt, 1993, 2002). So while Peirce's interpretants were divorced from animal corporeality, Morris's interpreters received their signs with real eyes and ears.

Morris's most lasting concerns may seem obvious in retrospect, but he deserves credit for having promoted them when both modern psychology and semiotics were in their formative stages. There was little novelty in his 'programmatic announcements'; nobody in linguistics, often an inspiration for the rest of semiotics, had ever doubted that the sounds of language are emitted by real tongues and vocal cavities. But his insistence that **all** signs habitually sent and received derive their 'vehicles' from the physiology of their senders and receivers proved influential

Charles W. Morris (1901–1979), who spent most of his scholarly life at the University of Chicago, influenced both semiotics and linguistics from the 1930s through the 1950s. In semiotics he formed a bridge between Charles S. Peirce's abstractly tenebrous works and the foundation in 1962 of the modern discipline, with its growing scientific emphases; in linguistics he promoted pragmatics, the study of language as people actually use it. To both disciplines he brought the belief that the study of signs would advance the unity of science; this faith, which his best-known student later conceded was largely restricted to "programmatic announcements" (Sebeok, 1979: 65), was advanced in his 'Foundations of the theory of signs' (1938) – a chapter in a volume entitled *Foundations of the unity of science: toward an international encyclopedia of unified science* – and in later works such as *Signs, language, and behavior* (1955) and *Signification and significance* (1964). The 'unity of science' now seems a rather quixotic endeavor, but Morris's ecumenical influence can still be discerned wherever biologists characterize how other creatures (and even plants) signal to one another (e.g., Frings and Frings, 1964; Sebeok, 1968; Krampen, 1981) and in the semiotic notion that the means by which biotic sign users send and receive signs is a cardinal aspect of signs themselves (for Morris, their 'sign-vehicles'). In this respect Morris argued for charging Peirce's notion of the interpretant, an abstraction, with physical reality, thus beneficially altering the modern notion of semiosis, the transmission of signification, so that it acknowledged that sign-vehicles are affected by brains and bodies. This view led ultimately to cognitive semiotics and an examination of how signs owe their forms to their senders' and receivers' (neuro-)anatomies (Watt, 1993, 2002). So while Peirce's interpretants were divorced from animal corporeality, Morris's interpreters received their signs with real eyes and ears.

Morris's most lasting concerns may seem obvious in retrospect, but he deserves credit for having promoted them when both modern psychology and semiotics were in their formative stages. There was little novelty in his 'programmatic announcements'; nobody in linguistics, often an inspiration for the rest of semiotics, had ever doubted that the sounds of language are emitted by real tongues and vocal cavities. But his insistence that **all** signs habitually sent and received derive their 'vehicles' from the physiology of their senders and receivers proved influential

within semiotics during and after the transitional decades he dominated.

Morris promoted another advance over Peirce's central foci when he evinced an interest in the relations obtaining within semiotic systems between sign and sign (see e.g., Morris, 1938: 84–85, 1955: 217–219). Such sign–sign relations, the very sinew of the morphologies and syntaxes of languages, prove to bind together other semiotic systems as diverse as alphabetic letters (Watt, 1981), Chinese characters (Wang, 1983), and heraldic arms (Mounin, 1986).

In sum, though all of Morris's writings on semiotics might now be viewed as having been at the level of tutorials, they were nevertheless influential at a time when just such tutorials were what was needed.

Morrobalama

S Ogilvie, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Morrobalama (Umbuygamu) is an endangered Australian Aboriginal language of the Cape York Peninsula in northern Australia. Originally spoken in Princess Charlotte Bay on the eastern coast of Cape York, its speakers were forcibly displaced from the region in the early 1960s. A handful of remaining speakers now live in the Cape York towns of Umagico and Coen. Morrobalama is atypical of most Australian languages in its phonemic inventory but typical in all other respects: it is nonprefixing with nominal case inflections, verbal inflections, and pronominal cross-referencing. It has free word order with a complex verbal structure that includes a fixed order of verbal stems, tense/aspect markers, and pronominal clitics.

With the other languages of the Princess Charlotte Bay region – Lama-Lama, Umbindhamu, Rimanggudinhma (Mbariman-Gudhinma), and the Flinders Island language – Morrobalama forms a subgroup of the northern Paman languages known by some linguists as the 'Lamalamic' languages or 'Bay Paman.' While speakers of the language refer to it as 'Morrobalama,' it is also called 'Umbuygamu' in the neighboring Umpila language, and this name had been used by linguists for many years. 'Morrobalama' is now the name preferred by both speakers and linguists (see Dixon, 2002: xxxi).

Australian languages are known to be relatively homogeneous in their phonemic inventories. Typically they display four to six paired stops and nasals (labial, apico-alveolar, apico-postalveolar, lamino-dental, lamino-palatal, and dorso-velar), two rhotics (trill and retroflex), no fricatives, no voicing contrasts, and a three-vowel system. In contrast, Morrobalama has a large phonemic inventory that includes atypical sounds such as fricatives, prestopped nasals, voicing contrasts, and a system of five vowels that contrast in length. More thorough analysis is needed of the sound system, but it may have seven places of articulation, including two laminal series (dental and palatal), three rhotics (two of which contrast in voice), two glides, and a glottal stop which is only found in a few other Australian languages (in western Australia and in Arnhem Land). While a typical Australian inventory

within semiotics during and after the transitional decades he dominated.

Morris promoted another advance over Peirce's central foci when he evinced an interest in the relations obtaining within semiotic systems between sign and sign (see e.g., Morris, 1938: 84–85, 1955: 217–219). Such sign–sign relations, the very sinew of the morphologies and syntaxes of languages, prove to bind together other semiotic systems as diverse as alphabetic letters (Watt, 1981), Chinese characters (Wang, 1983), and heraldic arms (Mounin, 1986).

Morrobalama (Umbuygamu) is an endangered Australian Aboriginal language of the Cape York Peninsula in northern Australia. Originally spoken in Princess Charlotte Bay on the eastern coast of Cape York, its speakers were forcibly displaced from the region in the early 1960s. A handful of remaining speakers now live in the Cape York towns of Umagico and Coen. Morrobalama is atypical of most Australian languages in its phonemic inventory but typical in all other respects: it is nonprefixing with nominal case inflections, verbal inflections, and pronominal cross-referencing. It has free word order with a complex verbal structure that includes a fixed order of verbal stems, tense/aspect markers, and pronominal clitics.

With the other languages of the Princess Charlotte Bay region – Lama-Lama, Umbindhamu, Rimanggudinhma (Mbariman-Gudhinma), and the Flinders Island language – Morrobalama forms a subgroup of the northern Paman languages known by some linguists as the 'Lamalamic' languages or 'Bay Paman.' While speakers of the language refer to it as 'Morrobalama,' it is also called 'Umbuygamu' in the neighboring Umpila language, and this name had been used by linguists for many years. 'Morrobalama' is now the name preferred by both speakers and linguists (see Dixon, 2002: xxxi).

Australian languages are known to be relatively homogeneous in their phonemic inventories. Typically they display four to six paired stops and nasals (labial, apico-alveolar, apico-postalveolar, lamino-dental, lamino-palatal, and dorso-velar), two rhotics (trill and retroflex), no fricatives, no voicing contrasts, and a three-vowel system. In contrast, Morrobalama has a large phonemic inventory that includes atypical sounds such as fricatives, prestopped nasals, voicing contrasts, and a system of five vowels that contrast in length. More thorough analysis is needed of the sound system, but it may have seven places of articulation, including two laminal series (dental and palatal), three rhotics (two of which contrast in voice), two glides, and a glottal stop which is only found in a few other Australian languages (in western Australia and in Arnhem Land). While a typical Australian inventory

consists of seventeen phonemes, the Morrobalama inventory has expanded to include thirty-six phonemes.

Morrobalama and other languages of Cape York have undergone phonological changes that may at first glance make them appear unrelated to other Australian languages. One such well-described change is the loss of the initial consonant (in the case of Morrobalama) or the initial syllable (in the case of other Princess Charlotte Bay languages). Thus, for example, **nyura* 'you (all)' has become *orha* and **nyulu* 's/he' has become *ola*. Initial dropping also occurs in other languages in separate parts of Australia, such as Nhanda in western Australia and Arrernte in central Australia.

Morphologically, Morrobalama is typical of most Australian languages in that it displays a split-ergative system: nouns operate in an absolutive/ergative paradigm, while pronouns are nominative/accusative. Thus in Morrobalama, absolutive is marked by zero on both the subject of an intransitive verb and the object of a transitive verb, and the ergative is marked by *-a* suffixed to the subject of a transitive verb. Pronouns have three numbers – singular, dual, and plural – and distinguish inclusive and exclusive in first-person dual and plural. They can occur both independently or bound, and when bound, occur as the final constituent of the verbal structure with the initial vowel dropped. So the independent pronoun *ola* 's/he' becomes bound as *-la*:

ola	nya – la – nan
3RD.SING.ACC	hit-3RD.SING.ACC. she-2ND. SING. OBJ. you
'she (emph.) hit you'	

This example also shows a typical Australian word-order feature: order is generally free, but there is a tendency for it to be based on pragmatic rather than grammatical principles, in which the emphasized phrase occurs first. In Morrobalama, all verbs must include at least a verbal stem plus a pronominal subject clitic; order of the clitics is free. Other suffixation on the verb marks tense, aspect, and mood (TAM). There is fixed order within the verbal structure (stem-TAM-PRO).

As is typical in Australian languages, Morrobalama derives new words via suffixes. For example, the comitative case *-pinh* acts as a lexical formative by being suffixed to a word to form a compound *x-pinh*, meaning 'with or having x':

ithi-pinh	lirrin-pinha	marr-pinh
bone-COM	smoke-COM	face-COM
('with bone')	('with smoke')	('with face')
'bony bream'	'steam boat'	'red-faced flying fox'

Most compounds, though, are of the 'general-specific' type, with stress falling on the specific element as though the general component acted as a clitic:

lam-eethal	lam-agaparr
hand-bone	hand-belly
'back of the hand'	'palm of the hand'

Morrobalama has not been passed on to the next generation, which speaks Cape York Creole (Torres Strait Creole) instead and, given the age of the few current speakers, it will probably disappear in the next decade unless intense language revitalization takes place.

Mother Tongue Education: Nonstandard Language

E Annamalai, Max Planck Institute of Evolutionary Anthropology, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

Historical Background

Mother tongue education became a political, pedagogical, and linguistic issue when formative education became in principle universally available to every citizen and formalized education came under the centralized control of the state in the modern period. It came then to refer restrictively to minority language education inclusive of minorities of endemic and migrant languages. The issue of mother tongue education came to the forefront during decolonization after World War II when the newly independent nations gave a new political and educational role to their native languages and when they formulated new policies about language use in education. The tendency of the new states was to give primacy to the mother tongue of the majority in education, and to designate it as the national language. The mother tongues of minorities, who were weak not just numerically, but politically and economically, too, were given a marginal place, or none at all, in education.

United Nations Formulation

The United Nations recommended in 1951 the favoring of mother tongue education for all linguistic communities through a UNESCO report that drew on the experience and research findings of experts and on its declaration of human rights, which proclaimed in 1948 that "everyone is entitled to all rights and freedoms...without distinction of any kind such as...language" (Article 2). This report, called *The Use of Vernacular Languages in Education* (UNESCO, 1953), is the basis of subsequent developments in educational policy and programs in mother tongue education around the world. Mother tongue education in this report includes development of literacy skills in the mother tongue and development of subject knowledge and skills through the mother tongue. The recommendation for using mother tongue in education, irrespective of speakers' political and economic position in the country they are living in, was reiterated in 2003 by UNESCO in its position paper titled *Education in a Multilingual World* (UNESCO, 2003). This reiteration draws its support for the earlier position on the use of mother tongue in education from various subsequent United Nations declarations and conventions such as Convention against Discrimination in Education (1960, Article 5), International Covenant on Civil and Political Rights (1966, Article 27), Declaration on Race and Racial Prejudice (1978, Article 9), Declaration of the Human Rights [of those] who are not Nationals of the Country in which they live (1985, Article 5), ILO Convention 169 concerning Indigenous and Tribal Peoples in Independent Countries (1989, Article 28), Convention on the Rights of the Child (1989, Article 29), International Convention on the Protection of the Rights of all Migrant Workers and Members of their Families (1990, Article 45), Declaration on the Rights of Persons belonging to National or Ethnic, Religious Minorities (1992, Article 4), Declaration on Integrated Framework of Action on Education for Peace, Human Rights and Democracy (1995, Article 19), and Universal Declaration on Cultural Diversity (2001, Article 6). All these documents sanction the right to learn and use one's mother tongue and, when combined with the right to education, cover the right to learn the mother tongue in schools and use it there. This recommendation made in different civil contexts shows that there is continuity in the international support for mother tongue education over half a century. There are, however, hedges and loopholes in the language of the recommendation to use mother tongue in education, which give enough room for states to procrastinate (Skutnabb-Kangas and Phillipson, 1994: 71–110).

Supporting Grounds

Mother tongue education is supported on ideological and pedagogical grounds. Ideologically, it is an aspect of language rights, which are a component of human rights and a way of protection from discrimination by language. Pedagogically, it aims to close the gap between language use at home and in school and to make seamless the progression of children from primary to secondary socialization. It also aims to improve academic performance and to develop positive attitudes in speakers about their linguistic and cultural heritage. Intergenerational transmission of language motivated by the pride of minorities in their language by use in a public domain is critical for the maintenance of language and cultural diversity in the world.

Definitional Problem

Two questions about mother tongue education give rise to interminable debate and delay in its execution. The conceptual question is how to define and identify a mother tongue. There are multiple interpretations of the term (Skutnabb-Kangas, 1981: 12–57), which

include the language in which one has primary competence, the language which gives identity and a sense of belonging, the language used extensively in daily life, and the language one learned first at home. Each of these meanings may assign a different language to be the mother tongue of a person. The other problem is of multiple identity with, equal competence in, and simultaneous acquisition of more than one language. In a multilingual situation, speakers have a repertoire of languages, which meet these criteria differently, and not one mother tongue. The solution is to leave the choice of the mother tongue for education to the speakers, not to the state. The programmatic question is how long the mother tongue will be taught as a language in school and used as a medium of instruction there. It is possible, even desirable, to teach the mother tongue as a language even after it ceases to be a medium of instruction. The decision about duration is normally decided by the state through political and economic considerations. The political consideration may express itself in pedagogical terms through disputable notions such as language load and unequal distribution of load between majority and minority language speaking students (Srivastava *et al.*, 1978). The view gaining greater acceptance among linguists and activists is that the rights and desires of the linguistic community about the introduction and duration of mother tongue education must outweigh the concerns of the state.

As mother tongue in the context of education refers to minority mother tongue, the definitional problem of the qualifying term minority raises legal questions of interpretation. Because it is a relational term, the question of frame of reference being the country, the state, or the county arises. There is also legal differentiation among kinds of minorities, and international laws apply differently to them (de Varennes, 1996: 129–173).

Various Models

The various models of mother tongue education address in different ways the questions of purpose, duration, and load about mother tongue education. All of them share the goal that it should not exclude the learning of the majority language, which is most likely the official language of the state, in which the government is run, and the dominant language for the political and economic advantages it grants to its speakers. The education models integrate the dominant language in some way in a bilingual education program. They, differ, however, on the goals of using the mother tongue in education. The difference lies basically in using it as a means of learning the dominant language and also viewing it to be an end in itself, such as promoting diversity in world view and creativity.

A long-standing model is bilingual (or multilingual) education (Crawford, 1995), in which the use of two (or more) media – the mother tongue and the dominant language – in the educational process, is combined in different ways motivated by ideologies and sociolinguistic situations in which the mother tongue is located. One basic difference between the models is whether the mother tongue and the dominant language are used simultaneously as the media of instruction by distributing them over the subjects taught or used sequentially starting with the mother tongue and switching over to the dominant language. In the former, either set of students can have their mother tongue or their non-mother tongue as the medium. The second variation is called immersion learning, which aims at students mastering the non-mother tongue, i.e., as a second language. This works when both languages have comparable economic, social, and cultural importance for their speakers as, for example, French and English do in Montreal (Lambert and Tucker, 1972). This is more a model for additive bilingualism through second language learning than for education in the mother tongue. The model that uses the medium of mother tongue minimally is the one that uses the mother tongue when teaching the language itself and not any other subject. This is a model for first language learning and not for use of mother tongue in education. Medium of instruction in a language comprehensively refers to the use of that language in teaching materials, classroom interaction, and examination. Use of the mother tongue only in classroom interaction by students does not qualify it to be a bilingual education model.

Experimental Results

The models were tested in different parts of the world and gave widely varying results with regard to academic achievement in the languages and the subjects (Cummins, 1981: 3–49; Rivera, 1984; Srivastava and Ramasamy, 2001: 29–43). The results relating to personality development and attitude toward mother tongue also vary. The variations in findings relate to variables such as the status difference in the two languages, socioeconomic background of students, community involvement, commitment of the teachers and the educational establishment, and so on. One universal finding, however, is that bilingual education aids acquisition of strong literacy skills in both the mother tongue and the dominant language (Swain *et al.*, 1990). Another repeated finding is that community involvement greatly contributes to

successfully achieving the objectives of bilingual education (May, 1999).

Resistance

In spite of consensus among the states, the shared opinion of experts in linguistics and education, and important positive findings of bilingual education experiments, there is resistance to mother tongue education at political, bureaucratic, and community levels. The political concern is the presumed threat of mother tongue education to national unity by hindering assimilation of the linguistic minorities with the majority and by the minority recipients making claims for territorial autonomy or devolution of power. But the historical evidence is that non-recognition of the minority mother tongue has led to conflicts and separation in a polity that otherwise allows its people freedom of expression. The bureaucratic reluctance stems from the mistaken notion that the minority mother tongues often do not have a grammar or literature to teach in the schools and that there is dearth of trained teachers who speak the mother tongue. This misses the logic of language development, according to which the grammar and literature come to be written down after the speakers become literate in the language; literacy in the mother tongue is a prerequisite for teachers to develop in the minority community. The apprehension about the cost in providing mother tongue education entertained by governments does not count the social cost of not doing it, of which the educational failure of the minority students is only a part. The solution suggested that, while the government has a supportive policy, the actual cost of mother tongue education should be borne by the minority community is discriminatory, which international declarations prohibit.

Community Response

The reservations of the minority community come from the suspicion that mother tongue education is a ploy of those in power to keep them perpetually marginalized, or the belief that their language is a liability for them to progress, which is ingrained subliminally in their minds by the negative articulation of the value of their language by the dominant language speakers. This reservation will disappear when they are convinced by non-partisan players in education that such fear and belief are unfounded empirically. The realization that mother tongue education is not exclusive of acquiring skills in the dominant language and that it actually aids its acquisition will bring in community support and involvement for the success of mother tongue education. Such awareness will also help the minority communities to exercise their right to the use of language in education prudently in favor of their mother tongue, and not in favor of the dominant language, as it is found in some places (Annamalai, 2000: 87–92).

Language Rights and Pedagogical Rationale

Mother tongue education stands on the two legs of linguistic human rights and pedagogical prudence. The two legs do not stand parallel when mother tongue stands as a symbol of identity without competence. When this is the case, teaching of the mother tongue (the right to language) and the medium of instruction (the right pedagogical tool) get separated. When the mother tongue is not the language of early childhood experience, i.e., the language learned competently at home and in the streets to relate oneself to the world, it is possible in the midst of this separation to teach the mother tongue as a new language and to use the language of early childhood experience for curricular instruction while the mother tongue gradually becomes the medium of life experience.

Mother Tongue Education: Standard Language

K S Goodman and Y M Goodman, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Education, ideally, should start in the mother tongue of the learners. That is the conclusion of research over more than half a century (UNESCO, 1953, 2004). Yet the reality of mother tongue education reflects more complex issues. Policies on which language (or languages) is used in primary and secondary education depends on political, social, economic and historic factors. An irony is that in former colonies the language of education is often the colonial language and not any indigenous mother tongue. There are several reasons for this:

- The existing educational system at the time of liberation used the colonial language.
- Those who had been previously educated, including teachers, had learned a colonial curriculum in a colonial language.
- The colonial language may be the only one in wide enough use to qualify as a unifying national language.
- It is economically and linguistically impractical to educate teachers and produce instructional materials in a range of mother tongues.
- The governmental, legal and business groups are likely to expect use of the colonial language.
- In South Africa, mother tongue education was a device used for segregation under the apartheid policies of the ruling party.

Children have a universal ability to learn the languages they need so in African countries, for example, it is common for children to know two or more languages before coming to school and then learn a new one in school.

In some countries, such as the Philippines, one official language may be used in instruction but not be the mother tongue of the majority of people. English still plays an important role there, and there is

Mother Tongue Education: Standard Language

K S Goodman and Y M Goodman, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Education, ideally, should start in the mother tongue of the learners. That is the conclusion of research over more than half a century (UNESCO, 1953, 2004). Yet the reality of mother tongue education reflects more complex issues. Policies on which language (or languages) is used in primary and secondary education depends on political, social, economic and historic factors. An irony is that in former colonies the language of education is often the colonial language and not any indigenous mother tongue. There are several reasons for this:

- The existing educational system at the time of liberation used the colonial language.
- Those who had been previously educated, including teachers, had learned a colonial curriculum in a colonial language.
- The colonial language may be the only one in wide enough use to qualify as a unifying national language.
- It is economically and linguistically impractical to educate teachers and produce instructional materials in a range of mother tongues.
- The governmental, legal and business groups are likely to expect use of the colonial language.
- In South Africa, mother tongue education was a device used for segregation under the apartheid policies of the ruling party.

Children have a universal ability to learn the languages they need so in African countries, for example, it is common for children to know two or more languages before coming to school and then learn a new one in school.

In some countries, such as the Philippines, one official language may be used in instruction but not be the mother tongue of the majority of people. English still plays an important role there, and there is

a policy of providing at least primary education in several regional mother tongues.

Countries with immigrant populations show variation in providing instruction in the mother tongue of each group. Singapore has four official languages: English, Mandarin Chinese, Tamil, and Malay. Hong Kong, now part of China, retains English and Cantonese for instruction though Mandarin is the national language. Some schools are switching from English to Cantonese. Britain has had a policy of providing mother tongue teachers where sufficient numbers exist in a school. Finland provides instruction in Finnish or Swedish though less than 10% of its citizens are Swedish speakers. Kazakhstan, a former Soviet Republic provides schools in Russian or Kazakh. Canada has two official languages, French and English, but also provides mother tongue immersion programs in indigenous Indian languages and European minority languages. In Haiti, the mother tongue instruction is not French but Haitian Creole. In nearby Aruba, however, instruction is in Dutch and not Papiamento, the Creole mother tongue.

All languages are actually families of dialects that are, more or less, mutually comprehensible. When dialects are not mutually comprehensible, they are considered separate languages. For example in Spain, Catalonia has its own language that is not a dialect of Spanish and is now the language of instruction in some communities. What the Chinese refer to as dialects are actually related languages since a speaker of Shanghai dialect cannot understand a speaker of Cantonese.

So the issue of what is and what is not a mother tongue is not a simple one.

Standards and Conventions in Mother Tongues

Education, whether in national language or mother tongue, traditionally involves using 'a standard' or idealized prestige form. In Italy, the saying is standard Italian is Florentine Italian from a Roman mouth. The standard form of Arabic used in writing is no one's mother tongue. In fact, becoming literate in Arabic involves virtually learning a second language.

Language is both personal and social invention. All humans have the ability to create language, to invent it. That is why there is so much linguistic diversity in the world. But language communities share conventions in order to serve their communicative needs. Children invent language as they develop within the conventions of the community language(s). We need to make a distinction between standard language and linguistic conventions as a base for a discussion of standard language.

- Language develops conventions for its use in all its aspects to serve its social functions.
- Conventions are based on and changed by the inventions of the language community.
- Language communities are not homogeneous; each group (age, race, ethnicity, region, profession, class) will develop its own conventions.
- Conventions allow for a high degree of variability which is resolved as users make sense of language.

Linguistic conventions and standard language are not the same thing. The term, standard language, carries with it nonlinguistic judgments. Different people within any community have different social status that may result from their economic, political, or religious positions. In England, high-status language is the Queen's English or Received Pronunciation.

Historically, conquerors imposed their language or dialect on the conquered people. By contrast, as rural people migrated to the cities, they continued to use their dialects because they lived separately from groups there before them.

It is not surprising that people have confused linguistic difference with linguistic deficiency. Its not surprising either that people believe that their neighbors will get along better and behave more acceptably if they learn to speak the 'standard language.'

What Is Standard?

The noun use of standard in English produced a verb form: to standardize, to make something uniform, and reduce variation. In industry, things that are not standard are neither good nor bad, though they may be problematic. Most of us would prefer a custom-made car, suit or dress, or house to a standard one. But in discussing language, the standard becomes the epitome of quality. That leads to terms like substandard and nonstandard to characterize everything or everyone else.

Napoleon created the French Academy to standardize the French language. Spain has its Royal Academy. Israel established an Academy to control the transition of Hebrew from a classical language to a living language. But no authority has ever succeeded in standardizing language. Even where there are official bodies, the standards they establish involve nonlinguistic factors. In Israel, often by the time the Academy has announced a standard term, popular terms have already become conventional.

Standard language does not match the conventions of any dialect in use, partly because of the aspects of dynamic change. Standard language is a myth that fits a powerful popular belief. It is that linguistic correctness has an existence outside of the normal processes

of language development. Partly that is because of the desire of upwardly mobile people to sound like people with prestige. Partly that is because of traditions that assigned the schools the job of socializing every pupil into a standard language and culture. Scientific linguistic concepts have had a hard time penetrating a curricular tradition that legitimates the imposition of school grammar on the living language of pupils.

Standard Spelling

Spelling is the one area in which standardization has been most successful. Standard spelling facilitates the work of printers and serves the needs of writers. Printers chose to standardize spelling across dialects rather than print different editions for each community. Noah Webster led a group who wanted to see the development of an American literature distinct from British literature. So he deliberately used spelling in his dictionary that differed from British spellings.

But standardizing spelling involves a trade-off. Alphabetic writing builds into the orthography some level of correspondence to the phonology of a language. But phonology varies greatly among dialects. By opting to standardize spelling, deviations from the alphabetic principle result. And over time the deviations become greater. The Scandinavian languages, Danish, Swedish, and Norwegian, although closely related, have spelling standards that differ considerably from each other.

Children learning to read and write with standardized spelling face a linguistic anomaly. An important part of learning language is moving toward the conventions of the social language. Within dialects, these conventions are quite consistent. So learners test out their inventions against the conventions of the language they hear. Standard spellings cannot match young readers' and writers' inventions. In fact studies of the invented spellings of young writers show their remarkably keen perceptions of the oral language as they hear it. (Read, 1975, 1986; Ferreiro *et al.*, 1996) Their consistent inventions show their growing control of the alphabetic principle: that there is a systematic correspondence not simply in matching sounds and letters; rather they match spelling patterns and phonological patterns.

Reading plays a major role in learning standard spellings. Readers see spellings that do not match their inventions and move to the standard forms in their writing. It takes a lot of reading and writing to become a conventional speller. Inhibiting the willingness of readers to take risks and invent spelling gets in the way of this natural progression.

In writing his 18th-century English dictionary, Samuel Johnson warned lexicographers against the folly of thinking that they could fix language at a point in time and preserve it from change. Dictionary makers take on the job of recording the meanings and spellings of words in use at the time they are working. The myth of the dictionary as the arbiter of standard language turns reality on its head. Dictionaries record the words in use and attempt to represent their meaning to the users. But by popular mythology it is turned into the authority for deciding whether words may be used and how. A dictionary may be useful as a tool to check whether the meaning of a word encountered in reading fits the ones in the dictionary. Even professional writers may need to use words and not be sure of the standard spelling.

Written Language Standards

Many people see written language as a single standard form unlike oral language. In fact, this is an area in which conventions are most confused with standards. Within written genre there are often conventions accepted by those that use the genre. There are conventions for essays, short stories, menus, business letters, receipts, and recipes. However formal these are, their conventions have been socially constructed and they change overtime. Authorities may presume to tell people how to write a business letter, how to write a novel, or a five-paragraph essay, but each written genre has conventions quite independent of such authorities. Often, attempts by schools to impose standards for a particular written genre lead to unsuccessful writing.

Schools and Standard Language

Schools traditionally have been regarded as having the right and duty to standardize the language of their pupils, often rejecting the language of the learners as substandard. In this view, difference is deficiency – even the differences in the ways high-status dialects vary from the school grammar. Too much time and energy is spent on teaching such standard features as avoidance of double negatives in English, for example. In reading instruction, children are corrected for use of their home dialect. In writing, some strange standards are taught that have no basis in the actual conventions, such as "do not end sentences with prepositions." Disproportionate instructional time is spent on the form of language to the exclusion of meaningful expression.

Although it is a school goal to support learners in developing the flexibility to use a range of registers in multiple contexts, it is not their function to standardize language. Schools should help pupils to be confident, effective language users. Developing readers

should read for pleasure and a full range of other functions. They should learn to write confidently and develop their own voices; and they should expand on their ability to speak and understand spoken language(s). In school, learners should feel free to take risks in language and experiment with new forms, words and styles. None of this translates into the rigidity of traditional school standards.

Supporting Language Development

Whether they teach in the mother tongue or in a national language, school language curricula should support expansion of language, building on the mother tongue of the learners. In language development at all levels, there is constant disequilibrium between the inventions of the learner and the conventions of the language. Learners should be encouraged to take risks as they learn a new language or as they use new forms of their first language or a new genre. In this push and pull they move toward the conventions of the language form and use it successfully. Language learners should be encouraged to study language variation in their own communities. Students take on the role of linguists as they inquire into language processes and their uses.

Schools have tended to suppress linguistic invention pushing learners toward an oversimplified or misrepresented version of the conventional language. Rather, pupils should be invited to participate in authentic speech acts and literacy events in which they encounter socially constructed conventions. Teachers can play a powerful role in demonstrating the conventions in their own authentic language use and in mediating the students as they experience the richness of language in its multiple forms and functions.

Motivation and Attitudes in Second Language Learning

R C Gardner, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

The concepts of motivation and attitudes have been associated with individual differences in second language learning since at least the 1950s, and over the years numerous perspectives and issues have developed. The corresponding research has been intensive and varied, and today there exist many different constructs and theoretical models seeking to explain individual differences in second language learning and use. The intent of this article is to consider the area in general, to discuss some of the more dominant perspectives and theoretical models, and to review some of the issues that are of interest to researchers and educators in this field.

Motivation Defined

The term motivation is used in the area of language learning with many definitions, processes, and measures proposed, and this variety is shared with the general area of psychology. In the early history of psychology, motivation was considered variously in terms of reinforcement, instincts, expectancy, valence, needs, and drive reduction. Recently, there has been more of a focus on process-oriented conceptualizations, including but not limited to curiosity, self-determination, causal attributions, and goal setting.

Some of the conceptualizations referred to above are represented in one form or another in the area of motivation in second language learning, and there have been calls for more attention to be given to others (see, for example, Crookes and Schmidt,

should read for pleasure and a full range of other functions. Motivation and Attitudes in Second Language Learning

R C Gardner, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

The concepts of motivation and attitudes have been associated with individual differences in second language learning since at least the 1950s, and over the years numerous perspectives and issues have developed. The corresponding research has been intensive and varied, and today there exist many different constructs and theoretical models seeking to explain individual differences in second language learning and use. The intent of this article is to consider the area in general, to discuss some of the more dominant perspectives and theoretical models, and to review some of the issues that are of interest to researchers and educators in this field.

Motivation Defined

The term motivation is used in the area of language learning with many definitions, processes, and measures proposed, and this variety is shared with the general area of psychology. In the early history of psychology, motivation was considered variously in terms of reinforcement, instincts, expectancy, valence, needs, and drive reduction. Recently, there has been more of a focus on process-oriented conceptualizations, including but not limited to curiosity, self-determination, causal attributions, and goal setting.

Some of the conceptualizations referred to above are represented in one form or another in the area of motivation in second language learning, and there have been calls for more attention to be given to others (see, for example, Crookes and Schmidt,

1991; Oxford and Shearin, 1994). Dörnyei and Ottó provided a formal definition of motivation as "the dynamically changing cumulative arousal in a person that initiates, directs, coordinates, amplifies, terminates, and evaluates the cognitive and motor processes whereby initial wishes and desires are selected, prioritised, operationalised, and (successfully or unsuccessfully) acted out" (1998: 65). This is a very comprehensive definition but it might not be accepted by all researchers. In fact, in his excellent book on motivation and second language acquisition, Dörnyei pointed out that most agreement would be obtained from researchers that motivation concerns the direction and magnitude of behavior, and that it is "responsible for *why* people decide to do something, *how long* they are willing to sustain the activity, and *how hard* they are going to pursue it" (2001: 8; italics in the original). This latter characterization is closer to that proposed by Gardner, who defined motivation in second language acquisition as "the combination of effort plus desire to achieve the goal of learning the language plus favourable attitudes toward learning the language" (1985: 10).

Attitudes Defined

The term attitude is also used quite extensively in the language-learning literature, and it too has a very large number of associated linkages. An early definition proposed by Allport in 1935 characterized attitude as "a mental and neural state of readiness, organized through experience, exerting a directive or dynamic influence upon the individual's response to all objects and situations with which it is related" (Allport, 1954: 45). Attitudes are considered to have cognitive, affective, and conative components and can be further characterized in terms of their direction, magnitude, intensity, ambivalence, cognitive complexity, embeddedness, flexibility, salience, and consciousness (cf., Scott, 1968). In terms of standard attitude measurement techniques, however, the assessment of attitudes tends to make use of questionnaires that focus on evaluative reactions to the attitude object. Thus, Gardner proposed that "an individual's attitude is an evaluative reaction to some referent or attitude object, inferred on the basis of the individual's beliefs or opinions about the referent" (1985: 9); reference to beliefs and opinions is made because of the way in which they are typically measured, though obviously attitudes also can be inferred on the basis of other aspects of behavior as well. Consideration of the two concepts, attitude and motivation, makes it very clear that they are closely interrelated. Motivation has attitudinal components, and attitudes have motivational implications, and the bulk of studies in the area of second language acquisition tend to recognize this interrelationship.

Theoretical Conceptualizations of Motivation in Second Language Learning

The definition of motivation proposed by Dörnyei and Ottó (1998) is important because it highlights the many features of motivation in terms of its dynamic nature, its continuity over time, and its implications for the task at hand. Similarly, Allport's (1954) definition of attitude provided a clear insight into its dynamic nature, notwithstanding its overall continuity as well. It is clear that both constructs are complex, interrelated, and implicated in most behavioral activities, and this is reflected in the research on individual differences in second language acquisition. A close inspection of the literature will reveal that although many researchers are concerned with the role played by attitudes and motivation, there are a number of different trails that have been followed. That is, there are conceivably a very large number of possible attitudes (in terms of attitude objects) and motives (in terms of reasons for doing an activity) that might be investigated. Moreover, each of these can be considered in terms of at least three different and distinct levels of analysis and generalization. In the area of motivation to learn another language, these can be classified in terms of three perspectives, societal, activity-centered, and individual.

Perspective I

The societal perspective of motivation focuses on community-level reasons for learning a second language. Because of different social and political exigencies or historical precedents, different cultures or national groups have different pressures on them to learn other languages or to attempt to revive or maintain their own language. In fact, the societal level was perhaps one of the first approaches to the concept of motivation in second language acquisition. In the lead article of the inaugural issue of *Language Learning*, Marckwardt identified five motives for learning another language, and at least four of them focus more on societal reasons than on individual ones. The primary one, and clearly the more individualistic, is for self-cultural development, viz., "a knowledge of modern languages is one of the accomplishments of a cultivated man" (1948: 3). The others refer to such societal reasons as maintaining the ethnic identity of a minority group, assimilation of an ethnic minority, promotion of trade and commerce, and scientific and technical usefulness. The actual descriptions of the motives clearly place emphasis on why individuals should learn other languages for the good of the

community. In all five cases, these motives can be seen as pressures placed by society on individuals to learn another language.

Societal motives are sometimes mistaken for individual ones, either by the researcher or by the individual student. Thus, when students state that their reason for studying a language is to obtain a degree, or to meet an academic requirement, etc., they are not really reporting on a motive of their own, but rather are voicing pressures exerted by society. In some of the literature, these types are described as extrinsic motives, but they are really pressures imposed by society. They could be considered motives that have been internalized by the individual if they are linked to other aspects of motivation; otherwise they are best characterized as reflecting external pressures. The important point is that motives are named on the basis of the reason for engaging in the particular activity, but motivation involves a series of related consequences such as effort, persistence, interest, and enjoyment. Without these, a reason is just a reason, not a motive.

Perspective II

The second perspective treats motivation as a characteristic of the individual that is tied directly to the task at hand. Constructs associated with this type of model are state motivation, which refers specifically to the motivation to do well at a specific time (cf., Gardner *et al.*, 2004; Heckhausen, 1991), and "on-line motivation" (Boekaerts, 2002), which focuses on the task itself and includes emotions, appraisals, and intentions before the task begins and emotions, attributions, and effort reported at the end of the task. Elements of these constructs are represented in many models, but one model that focuses directly on the task of language learning is that proposed by Dörnyei and Ottó (1998). It consists of three phases: preactional, actional, and postactional. It is a model that treats motivation in very conscious terms. Individuals have objectives, set goals, perform acts, experience their outcomes, appraise their success, and behave accordingly. It is an informative analysis of what takes place at specific stages of learning and as such provides very useful perspectives for individuals concerned with explaining specific behaviors in language learning. It does not, however, deal with aspects of motivation of which the individual is unaware (unconscious features) or long-range motivation.

Perspective III

The third perspective has been characterized by Dörnyei (2001) as comprising two different approaches. One focuses on social motivation that treats second language acquisition as a task closely linked with self-identity and ethnic relations. The other is described as "education-friendly" and focuses on the individual and classroom interactions. Both treat the motivation to learn the language in terms of relatively stable affective characteristics. That is, motivation to learn another language is seen as a general disposition of the individual that nonetheless may be influenced by a number of external factors.

One of the earliest studies based on the social motivation approach was conducted by Gardner and Lambert (1959), based on Lambert's seminal research and theorizing on bilingualism (see, for example, Lambert, 1955, 1967). In their study, Gardner and Lambert demonstrated that two factors, language aptitude and motivation, were associated with achievement in French among a sample of English-speaking high school students. The motivation factor was characterized by a high level of motivational intensity to learn French, favorable attitudes toward French Canadians, and a preference for integrative as opposed to instrumental reasons for learning the language – the so-called integrative–instrumental dichotomy, which subsequently became a topic of much discussion (see below).

There have been a number of models that have developed from this tradition. One of the earliest was the socioeducational model of second language acquisition (Gardner and Smythe, 1975; Gardner, 1985). The basic assumption underlying this model is that language is a significant part of one's self-identity and that learning another language is much more complex than learning another school subject because it involves "the acquisition of skills or behaviour patterns which are characteristic of another cultural community" (Gardner, 1985: 146). In the socioeducational model, second language learning is seen to take place in the context of a series of antecedent experiential and biological factors (such as the sociocultural milieu, and prior educational experiences, gender, etc.) which act on a host of individual variables. These individual difference variables in turn act in conjunction with formal and informal language acquisition contexts to yield linguistic and nonlinguistic outcomes.

Although a number of individual difference variables, such as language aptitude, intelligence, language anxiety, instrumental orientation, and language learning strategies, are considered in the socioeducational model, the major attention is directed toward the concept of integrative motivation. The model proposes that two attitudinal factors, integrativeness and attitudes toward the learning situation, serve as supports for and influences on the motivation to learn another language and that motivation and language aptitude are two primary variables

influencing achievement. It also allows that other affective individual difference variables, such as language anxiety and an instrumental orientation, may influence second language learning. The constellation of integrativeness, attitudes toward the learning situation, and motivation has been described as reflecting an integrative motive to learn another language in that the integratively motivated individual is perceived as one who has an open interest in the other language community and other ethnic communities in general, perceives the language learning context positively, and expresses a high degree of motivation to learn the language. Associated with this model is the Attitude Motivation Test Battery (AMTB), which is designed to measure various features of the integrative motive as well as instrumental orientation and language anxiety, and has been used in many investigations in this area (see, for example, Gardner, 1985, 2000).

Clément (1980) proposed an alternative model that considered many of the same variables, but focused more attention on the social context and the relative vitality of the first- and second-language communities. Integrativeness and fear of assimilation were seen to influence the motivation to learn a second language in unilingual communities but to be mediated by the frequency and quality of contact and the resulting self-confidence in the language in multicultural contexts. Individual differences in motivation resulted in competence in the language, which in turn could influence the individual's level of acculturation. In subsequent research, this model has been modified and extended to deal with acculturation of ethnic minority group members (cf., Clément, 1986; Noels *et al*., 1996).

MacIntyre *et al*. (1998) proposed a Willingness to Communicate Model that is based on similar constructs as these models, but viewed the ultimate goal as willingness to communicate rather than achievement itself. This is an important development in this area in that it stresses that the ultimate goal is not to learn the language but to develop the competence and the confidence to use it in communication. Like the other models discussed in this section, it includes variables associated with integrative motivation. Also, like Noel's (2001) self-determination model (see below), it includes some personality characteristics, etc., but it places ultimate use of the language at the pinnacle of a pyramid and actual learning further down, whereas the other models treat ultimate communication more or less as a given of learning the language. As many language teachers will note, however, this is not a foregone conclusion.

Noels (2001) has proposed a model of second language acquisition based on Deci and Ryan's (1985) self-determination model. It considers both intergroup and individual motivational processes and links them to six classes of variables. These are immediate social contact, fundamental needs, orientations, intention and engagement, L2 use, and linguistic and nonlinguistic outcomes. In this model, proficiency in the other language is seen as a linguistic outcome resulting from the interplay of contact with the language with four fundamental needs, social identity, relatedness, autonomy, and competence leading to three orientations, integrative, intrinsic, and extrinsic. These in turn can influence the willingness to communicate and the effort and persistence demonstrated in learning the language, which in turn leads to language use and ultimately proficiency and some possible changes in identity. As can be seen, this model is comparable to the others discussed above, although, as with the willingness to communicate model, it is perhaps more detailed in that it explicitly identifies many variables that might be implicated in language learning. The overlap is recognized by Noels, who claimed that "The primary contribution of this approach lies in that it figuratively takes a magnifying glass to look more closely at the nature of orientations, how they are affected by significant others in different contexts, and how they may be differentially related to L2 variables" (2001: 61).

These models vary in terms of parsimony, with the socioeducational and the social context models being the most parsimonious in that they involve fewer variables and processes than the others. They are all similar, however, in that each of them recognizes that second language acquisition involves the acquisition of features that are characteristic of a different culture. This in turn could have implications for feelings of self-identity for some individuals.

The education-friendly models place more of an emphasis on characteristics of the individual, and the implications this can have for learning, and focus on variables that could be appropriate to any learning situation. Dörnyei (2001) described a number of such models, some of which are drawn from other fields of psychology, including educational psychology. One example of such a model is Dörnyei's (1994) "extended motivational framework." This model considers motivation in terms of three levels, the language level, the learner level, and the learning situation level, and proposes that each of them can supplement or cancel the motivation generated at the other levels. The language level focuses on motivation associated with the language itself (i.e., the community, value of knowing the language, etc.); the learner level refers to characteristics of the student similar to the social motivation models; and the learning situation level focuses on motivation deriving from the curriculum, the teacher, and the classroom.

Another example of an education-friendly model is the social constructivist model proposed by Williams and Burden (1997). This model distinguishes between internal factors, such as the individual's intrinsic interest, perceived value, feelings of competence, and attitudes about the language, and external factors, such as significant others, the learning environment, and the social context. This model includes a large number of variables that could be implicated in the language learning situation that would be of particular interest to teachers and educators who wish to consider various aspects that could influence an individual's level of achievement in the language.

Each of these models is useful in helping us understand the learning process, in making us aware of variables that can influence learning, and in suggesting perspectives that we might embrace. It is important to note, however, that the models are not contradictory. None makes a prediction that is not consistent with the others. The models do differ somewhat in the specificity of the processes involved, varying from statements about how variables in the model influence or effect others to largely a description of variables or classes of variables that can be involved. They also differ in terms of the amount of research that has been devoted to testing specific predictions deriving from them. Clearly, there are a number of different ways of conceptualizing motivation in second language acquisition and in the types of attitude variables that might be implicated. An interesting question, however, is whether or not they capture different sources of variation in second language achievement. That is, each of them postulates the importance of somewhat different constructs and processes, but to the extent that they all are concerned with explaining the role of motivation in second language learning, one might well ask whether any one model would contribute to prediction over another or whether the ultimate degree of prediction of achievement would be essentially the same regardless of the model followed. If this is the case, the value in the model rests not so much in accounting for variation in achievement but in the nature of the variables to be emphasized.

Issues

There are many questions that have been raised by researchers and educators about the role of motivation and attitudes in second language acquisition, and at least five of these have become issues that are relatively central to this area of research.

One very basic question deals with the direction of causation between attitudes and motivation on the one hand and language achievement on the other. It is implied in many of the models that individual differences in motivation are responsible in part for differences in achievement, but it has been questioned whether this is the most meaningful cause–effect sequence. One could equally argue that achievement in the language promotes motivation and favorable attitudes (cf., Ellis, 1994). When dealing with the relationship between individual differences, however, it is not possible to demonstrate simple causation of the nature that A causes B. The only way to demonstrate such causation is to randomly assign individuals to the various values of A and to assess whether this results in variation in B (cf., Gardner, 2000). The attempt to use procedures such as structural equation modeling to demonstrate the direction of causation is not a solution. Such 'causal models' are not tests of causation, but simply tests of one way of explaining relationships in terms of regression coefficients. This is a big difference! With characteristics that individuals bring with them to any situation, random assignment is not possible; hence, unequivocal conclusions about causation are not possible. Though this may seem like a major problem, in point of fact, the direction of causality is immaterial. To the extent that there is a correlation between motivation and achievement in the population, this means that there are conditional (Bayesian) probabilities linking the two variables. For example, a positive correlation demonstrates that there is an increased probability that an individual with high levels of motivation will be more successful in learning the language than an individual with low levels and there is also an increased probability that the individual who is successful in learning the language will be more motivated to learn the language than an individual who is less successful.

This can be demonstrated by an example from a study we recently conducted in Spain (Gardner and Bernaus, 2004). In that study, a correlation of 0.40 was obtained between motivation assessed in the autumn and the following spring grades in English among a sample of 166 Level 2 secondary school students. Further analysis revealed that the probability that individuals scoring above the median in motivation would be in the top 30% on achievement was 0.40, whereas the probability was 0.19 for those scoring below the median on motivation (i.e., twice as great). Similarly, those above the median on achievement were more likely to be in the top 30% of motivation with a probability of 0.37, whereas the probability of those below the median on achievement being in the top 30% on motivation was 0.23 (again close to twice (1.61) as great). These are not certainties, of course, and could vary from sample to sample, but they do indicate clearly

that a correlation as low as 0.40 has clear implications about the conditional probabilities that operate when it is established that there is a correlation between two variables.

A second, but related, issue involves the degree of relationship between the two classes of variables. It is true that a correlation of 0.40 between motivation and achievement indicates that only 16% of the variation of one of the variables is explained by the other (cf., Ellis, 1994; Dörnyei, 2001), and as a consequence, some researchers consider low correlations to be trivial. The first part of this statement is true; the last part is arguable. Cohen described a correlation of 0.30 as reflecting a medium effect and that such a relationship "would be perceptible to the naked eye of a reasonably sensitive observer"(1988: 80). He noted too that "many of the correlation coefficients encountered in behavioral science are of this magnitude" (1988: 80). Moreover, as indicated above, such a correlation still implies a level of conditional probabilities that are not trivial.

A third issue is long-standing and deals with the distinction between integrative and instrumental orientations. In their initial study, Gardner and Lambert (1959) classified students as integrative or instrumental in their orientation to studying French as a second language based on the reason they ranked as most applicable to themselves. The results demonstrated that individuals who were integratively orientated were more motivated, had more favorable attitudes toward French Canadians, and had higher levels of achievement in French than those who were instrumentally oriented. In subsequent research (e.g., Gardner and Lambert, 1972; Gardner and Smythe, 1975), this dichotomous measure was dropped in favor of separate measures of the applicability of each type of orientation to language learning. Although the results demonstrated that the two orientations were positively related to each other, many other researchers and educators tended to emphasize the relative superiority of one over the other (cf., Crookes and Schmidt, 1991; Oxford and Shearin, 1994). A meta-analysis conducted by Masgoret and Gardner (2003) demonstrated that achievement tended to be more highly related to individual differences in an integrative orientation than in an instrumental one but the differences were not large. In fact, the mean correlations were relatively low over all, though in the various samples, correlations with grades were as low as −0.21 and as high as 0.56. For three different types of achievement measure (grades, objective measures, and self-ratings), the mean correlations ranged from 0.15 to 0.20 for integrative orientation and 0.08 to 0.16 for instrumental orientation.

Some of the questions concerning the lack of importance of the role of attitudes and motivation in second language acquisition derive from individuals who focus only on the orientations (cf., Crookes and Schmidt, 1991) rather than considering the other attitudinal and motivational variables. All of the social motivation models include other attitude and motivation measures, however. In the socioeducational model, for example, Gardner (1985, 2000) stressed that motivation, not orientations, is the major affective variable implicated in second language learning, but that it is supported and maintained by integrativeness (as distinct from simply an integrative orientation) and evaluation of the learning situation. He has proposed (Gardner, 2000) that many factors might contribute to motivation, even though integrativeness will always be important because of the link between language, ethnicity, and self-identity.

A fourth issue has to do with the distinction between second and foreign language learning. Inspection of the literature reveals that there are at least two reasons for making such a distinction, one based on the availability of the language in the community (cf., Oxford and Shearin, 1994) and the other on the sociopolitical importance of the other language (cf., Dörnyei, 2001). It has been proposed that motivational and attitudinal variables would play slightly different roles in the case of a second as opposed to a foreign language learning context, but to date there has been little evidence to support such a hypothesis. For example, a meta-analysis of research conducted by Gardner and associates failed to detect an effect of bilingual vs. monolingual settings on the relationship between motivation and language achievement (Masgoret and Gardner, 2003). Furthermore, research conducted in Hungary, in which English is clearly a foreign (as opposed to a second) language, found significant relationships between integrative motivational types of variables and achievement in English (Dörnyei and Clément, 2001).

Perhaps the most dominant issue currently is the distinction between motivation and motivating and the implications that the education-friendly vs. the social motivational models have for this distinction. Education-friendly models highlight features that educators might use to motivate students. Close inspection of these models will reveal, however, that many of the features discussed are common to virtually any subject from mathematics to history (i.e., interest, intrinsic motivation, teaching techniques, course content, causal attributions, feedback, arousal of curiosity, feelings of competence, age, and gender). These are important attributes to be sure, but it is important to determine whether these models contribute anything to the prediction of achievement or related behaviors such as the willingness to

communicate that is not predicted by the social motivation models. Clearly, there is nothing in the education-friendly models that is inconsistent with predictions from the social motivation models, or vice versa, and the social motivation models could incorporate the other features without changing their basic assumptions or postulates.

The problem of motivating students is one that can be difficult in the context of second language learning if one accepts that such learning involves a construct such as integrativeness. In the socioeducational model (Gardner, 1985), integrativeness involves more than just an integrative orientation. It refers to the individual's cultural openness and interest in other communities and languages and favorable attitudes toward the target language group as well as an integrative orientation. Integrativenss is a higher-order construct with many levels. At one level, it can mean simply a willingness or capacity to take on characteristics of another cultural community. At another, it can reflect a full desire to identify and integrate with the other community. Most language learners do not study languages in order to become members of another cultural community (though some might), but at a minimum they must be able to make features (i.e., language) of another community part of their own behavioral repertoire, and there are individual differences in the ability (or willingness) to do this.

Two examples from the literature illustrate possible extremes of an integrativeness dimension. One, described by Nida (1956), was the case of an individual, the son of immigrants, who identified strongly with the American way of life and hid his immigrant background while growing up. Despite a superior language program and a strong motivation to learn a foreign language to aid him in his life as a missionary, he was unsuccessful in learning the language. Nida proffered that his earlier rejection of his immigrant background made him incapable of learning a foreign language. At the other extreme, Lambert (1955) described an American graduate student majoring in French who measured dominant in French on measures of bilingualism. This student had an extreme attachment with France, read French newspapers, etc., and planned to move there when he graduated. Although these are extreme examples, they serve to define the potential extremes of integrativeness from high negative to high positive and also indicate that the effects of integrativeness on motivation might well be unconscious. That is, individuals might want to learn a language but because of emotional issues associated with ethnicity simply may not be capable of doing so.

The construct of integrativeness has implications for the issue of motivating students. Educators may use procedures to motivate students, but these techniques may well be ineffective for some students, and it is important to conduct research to evaluate their effectiveness in motivating students to actually learn and use the language. Recently, we investigated attitudinal and motivational changes over a year-long course, and the results were instructive. Two studies were conducted, one with Canadian university students of French as a second language (Gardner *et al.*, 2004) and the other with EFL secondary school students in Spain (Gardner and Bernaus, 2004). In both studies, significant interactions were obtained between ultimate achievement in the course and time of testing for attitudes toward the learning situation but not for other attitudinal and motivational characteristics measured by the AMTB. In both studies, students who were ultimately successful in the course evidenced relative increases in attitudes toward the learning situation, whereas students who were least successful showed declines and the middle students showed virtually no change. That is, the degree of success in the course had an effect only on reactions to the course and/or the teacher. Admittedly, there was no attempt to investigate specific motivational techniques, but the teachers in the study, like most teachers, were quite likely doing their best to teach the students and to motivate them. In both studies, there was also a tendency for the measures of integrativeness and motivation to become less positive over the course of the year, but these changes generally were not moderated by ultimate success in the course. The implication is therefore that what goes on in the course can influence learning and reactions to the learning situation but not integrativeness or motivation. It is possible, therefore, that educators' attempts to motivate students could result in improved reactions to the course but not in more general attitudes, motivation, or the willingness to use the language outside the classroom environment. Clearly, much more research is required to investigate the issue of motivating students in language classes to determine whether or not it has the desired effect in terms of achievement and willingness to use the language. This is an important challenge for the future.

Motoori, Haruniwa (1763–1828)

M McCaskey, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Haruniwa Motoori (1763–1828) was the son of the great Japanese studies (*Kokugaku*) scholar Motoori Norinaga (1730–1801). Like his father, Haruniwa spent most of his life as a scholar, teacher, and medical therapist in the town of Matsusaka, northwest of the city of Ise, in modern-day Mie Prefecture. As a child, Haruniwa was totally devoted to Norinaga, helping to copy his father's manuscripts and prepare them for printing. He even assisted his father, who was also a physician, in preparing and prescribing herbal medicine. Devoting himself to learning Japanese studies from his father and other eminent teachers, Haruniwa began to develop a level of expertise in Japanese language, literature, and philology that Norinaga hoped would enable his son to become a leading Japanese studies scholar in his own right.

Unfortunately, Haruniwa's eyesight began to fail when he was in his late 20s. Despite the best medical attention then available, Haruniwa lost his sight completely by the time he was 32. Norinaga felt that Haruniwa's blindness would make it impossible for his son to function successfully as a scholar. Instead, he adopted Inagaki ōhira (1756–1833), the studious son of a local tofu merchant, and designated ōhira as his successor. When Norinaga died a few years later, Haruniwa accepted ōhira as the head of the household, and the senior scholar in the family. Even so, Haruniwa continued his own scholarly work, with the help of his wife and his sister, who read to him, recorded his research notes, and wrote down his manuscript pages as he dictated them.

Despite Norinaga's misgivings about Haruniwa's disability, Haruniwa spent the rest of his life carrying on his father's work in various ways. As an acupuncture therapist, he carried on Norinaga's medical practice in Matsusaka, and helped support the family. He also taught Japanese language, literature, and philology, attracting advanced students who helped transcribe his lectures and research for publication. He carried on Norinaga's literary and philological research on the 8th-century Japanese historical classic known as the *Kojiki* (Record of Ancient Matters.) With his students' assistance he also edited a large body of Norinaga's manuscripts for posthumous publication.

In the history of Japanese linguistics, Haruniwa is best known for two of his own original studies of Japanese morphology and syntax, *Kotoba no yachimata* (The crossroads of words),written in 1808, and *Kotoba no kayoiji* (The interaction of words), his final work, completed shortly before his death in 1828. *Kotoba no yachimata* was a large-scale morphological study of Japanese verb inflections that developed and systematized Norinaga's earlier ideas on the subject. *Kotoba no kayoiji* was a comparative study and classification of transitive and intransitive verbs, as well as of passive and causative inflections. These studies were the basis of development for the way these forms are taught in Japanese schools today.

Yachimata (The crossroads), a detailed 1974 study of Haruniwa's life and work by the critic Adachi Ken'ichi, finally gave this scholar his long-denied place in the history of Japanese linguistic studies. The fact that Haruniwa was able to achieve so much after he lost his eyesight makes him a remarkable figure in his time, when blindness was generally considered an insuperable disability. Haruniwa's courage and success in persevering with his linguistic research in such times deserves our greatest respect today.

Motoori, Norinaga (1730–1801)

M McCaskey, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Norinaga Motoori (1730–1801) was a leading Japanese studies (*Kokugaku*) scholar. He was a native of Matsusaka, a town northwest of Ise, in present-day Mie Prefecture. He was from a family of merchants with connections in Edo and Kyoto, and Norinaga visited both cities. His father's early death, family problems, and business losses made him self-reliant. He chose to become a physician, so he could be independent and support himself while continuing to develop his scholarly abilities.

In 1752 Norinaga went to Kyoto to study traditional medicine and humanistic subjects. He was attracted by the innovative historical and philological research done by Keichū (1640–1701) on the ancient *Manyōshū* poetry collection. Norinaga combined Keichū's methods with his own system of appreciating literature through the 'emotive perception of phenomena,' *mono no aware o shiru koto*. This focus on intuitive perception of the emotions and sentiments inherent in a text superceded the didactic and moralistic approaches then common. Norinaga's *Genji Monogatari tama no ogushi* (1793–1796), a detailed reinterpretation of the *Tale of Genji,* established a system of literary and textual analysis of this novel that endures to the present day.

In 1757, at the age of 27, Norinaga returned to Matsusaka. Supporting himself as a pediatric physician, he pursued linguistic, literary, and historical studies in his free time, giving lectures based on them to a growing number of students from the Ise area. Scholars began to come from Kyoto to visit as well. He wrote more than 40 books, based on his own research and lecture material. His advanced students compiled many more, during his lifetime and posthumously, from manuscripts and notes.

Japanese scholarship had traditionally tended to focus on texts from China, using centuries-old methods of analysis. Norinaga was part of a new generation of Japanese scholars who explored their own country's heritage instead. He admired the work of Kamo no Mabuchi (1697–1769), one of the founders of the Japanese National Studies movement, who came to visit him in Matsusaka. Like Keichū before him, Mabuchi analyzed the historical and linguistic features of the texts in the *Manyōshū*. Norinaga undertook analogous research on the *Kojiki* (Records of ancient matters), an 8th-century Japanese historical text. He spent more than 30 years compiling his monumental *Kojiki-den* (Commentary on the *Kojiki*), in forty-four volumes.

Norinaga also did original work in the fields of morphology and phonology, based on his analysis of classic Japanese literary texts. The *Kotoba no tama o* (Beads of jeweled words), completed in 1779, summarizes Norinaga's ideas on the functions of postpositional particles and verb inflections, with usage examples taken from Japanese literary texts. His *Jion kanazukai* (Phonetic uses of Chinese characters), written in 1776, is a study of how Chinese characters were adapted to serve as phonetic symbols in ancient Japanese texts. The *Kanji san on kō* (A study of the three phonetic uses of Chinese characters), completed in 1785, studied variations in phonetic uses of Chinese characters in Japan due to diachronic phonological changes in China.

While Norinaga's nationalistic approach in interpretation may no longer be accepted by most 21st-century literary critics and historians, conditioned as it was by his era, his careful methods of linguistic analysis still command the respect of scholars today, and his thorough textual annotations of the *Kojiki* and other classics will continue to be consulted and taken into consideration by modern translators.

Mounin, Georges (1910–1993)

P Martin

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, p. 2615, © 1994, Elsevier Ltd.

'Georges Mounin' is a pseudonym used for the first time by Louis Julien Leboucher in 1943 to escape censorship by the Vichy government, which had identified him as an active member of the French communist party and a Resistance fighter. The son of a glassworker, Delphin Leboucher, and of Julienne Lansoy, Mounin was born on June 20, 1910, in Vieux-Rouen-sur-Bresle, a small village in Normandy.

He married Julienne Montagné on September 18, 1930, and they had three children. After graduating from teacher-training college in Rouen (1929), Mounin held teaching positions at the primary and secondary school levels, in France and in Egypt. In 1946, he was named teacher of Italian at the 'Ecole normale des instituteurs' in Aix-en-Provence. In 1958, he was appointed to the 'Conseil national de la recherche scientifique' as 'Attaché de recherches,' and in 1961 he joined the University of Aix-en-Provence, where he remained until 1976, holding the positions of 'Maître assistant' (1961), 'Maître de conférences' (1965), and 'Professeur titulaire' (1966) of general linguistics, stylistics, and semiology. While in Aix, Mounin helped train a number of French and foreign students who later became recognized linguists. His working class origins, but more importantly the influence of French rationalism, no doubt account for his early involvement in communism. He was a regular contributor to *Lettres françaises, Vie ouvrière*, and *Action*, journals of the communist intellectuals. But the open-minded and prudent militancy that resulted in his contributing also to noncommunist journals such as *Esprit* and *Confluences* finally led him to a rejection of dogmatism when, in 1980, he officially abandoned the French communist party. He died on January 10, 1993 in Béziers.

In linguistics, Georges Mounin is a disciple of André Martinet (*see* **Martinet, André (1908–1999)**), the French functionalist. Mounin's contributions to linguistics are both numerous and varied, showing open-mindedness, and extensive and wide-ranging knowledge. An admirer, great reader, and sharp analyst of poetry, he has written penetrating studies which have opened up new perspectives on the scientific analysis of literary texts (see his frequent articles in *La pensée, La nouvelle critique, Les temps modernes*, and *Cahiers du sud*, as well as Mounin (1946, 1961, 1969, 1992). An impassioned Italianist, Mounin has repeatedly demonstrated his profound knowledge of Italian culture (1958, 1960, 1964b). His doctoral dissertations (Mounin, 1963, 1964a) placed him among the top theoreticians of translation (see also 1955, 1976). Mounin is also well known for his remarkable contribution to the history of linguistics (Mounin, 1967, 1972a, 1974). An excellent teacher and popularizer (1968a, 1968b, 1975a), semanticist and philosopher (1972b, 1970, 1975b, 1985), Georges Mounin has set a high goal for other linguists, that of combining versatility and profundity.

Mozambique: Language Situation

R M M Cumbane, Escola Superior de Educação Jean Piaget/Nordeste, Macedo de Cavaleiros, Portugal

Most Mozambican languages have no official written tradition. However, they are used in correspondence, songs, lyric poetry, and mostly in ecclesiastical contexts by a limited number of individuals who can read and write in their mother tongue. Some of these languages have a Bible and are broadcast by the state broadcasting station. The station keeps delegations in all the provincial capitals. State television does not broadcast in any national language, contrasting with emerging private television stations, which also broadcast in Xichangana (a dialect of Tsonga) and Xirhonga, two languages from south Mozambique. There are few periodicals published in Bantu languages, and the number of writers who have been published or had their works translated into those languages is equally small. Notwithstanding the fact that the Mozambique Constitution (paragraphs 5 and 6) sanctions the multilingual status of the country, no national language has been adopted as a working language in Parliament. The reason for this is to preserve the country's unity.

The Republic of Mozambique is a multiethnic and multilinguistic state in which, because of its history as a colony of Portugal, the official language is not the mother tongue of most Mozambicans, but rather the language of the colonizer, Portugal. Therefore, Portuguese language is the bridge between the different peoples that form the country (Table 1). In fact, 1980 census data (14 million inhabitants) and 1999 data (18 million inhabitants) revealed a heterogeneous country, formed by several ethnic groups and their subsequent divisions, all possessing different languages, cultures, values, and traditions. The political choice of Portuguese as the official language of Mozambique is not a recognition of the colonizer's cultural superiority; it is, rather, according to Graça Machel, a former Minister of Education,

> "a way of disavowing causes of division and national alienation, integrating it as a vehicle of social, political and economic communication . . ., turning it into a harmonious whole of the new national reality. . . . We must have in mind that, despite the colonization, national idioms have handed down and created Mozambican culture, propagating arts and techniques and the ancient knowledge of nature. In them were forged the words and concepts, forms, rhythms and the musicality which characterize the Mozambican being (NELIMO, 1989)."

Despite the Portuguese colonizers' attempts to destroy Mozambican culture, their inability to govern the whole territory allowed the oral transmission of knowledge to occur, from generation to generation, in rural areas. Later on, several factors led to unsolvable breaches in Mozambican life's natural scope, by killing knowledge holders – the elders, who were therefore also the most vulnerable: These included the civil war (1975–1992), past and present epidemics that killed specialized personnel (recent statistics show that 500 people become infected with HIV each day), famine, and natural disasters. Such factors, as well as the lack of qualified personnel for teaching the mother tongue and eternal and sensitive questions of sociolinguistic and political order, make the comprehensive and systematic teaching and development of national languages at school an almost impossible job. Though there are no data to prove it, the insidious entry of English language as a second foreign language of prestige in the country's capital (Portuguese is regarded as the first foreign language, despite the fact that some are advocating turning it into one of the national languages) used in business, tourism, and even in teaching makes it an even more complex job to value Mozambican languages.

The diglossia/assimilation policy followed by colonizers lasted for five centuries, before the seriousness of the delay was felt. Paixão's words (1948: 10)

Table 1 Percentage of Mozambicans who speak Portugese[a]

Age	*% Who Speak Portuguese*		
	Total%	*Men*	*Women*
Total population	39.6	50.4	29.7
5–9	23.0	23.7	22.3
10–14	48.6	52.0	44.9
15–19	52.5	62.7	43.2
20–24	47.6	61.4	37.2
25–29	45.8	62.0	33.3
30–34	48.4	66.9	32.6
35–39	43.1	65.0	23.9
40–44	37.7	59.2	18.5

Urban	72.4	80.7	64.2
Rural	25.4	36.6	15.6

[a]The calculations exclude the unknown population in relation to the knowledge of the Portuguese language.

Figure 1 Mozambigue's linguistic map.

regarding this matter are unmistakable: "Our mission towards the native is civilization and naturalization . . . we approach the native to turn him into another Portuguese."

If a return to a situation devoid of colonial influence is impossible, then it is up to Mozambican linguists and others to (1) describe the current situation of Mozambican languages, (2) preserve the languages through the building of grammars, (3) value the languages through teaching and literature, and (4) study those languages' interactions with the Portuguese language. Only objective (1) is the current focus of attention.

Linguistic Network

Problems

Mozambique has a multiplicity of languages, which correspond to several ethnic groups. For example,

Xithwa is spoken by the Mathwa, Cisena (Sena) is spoken by the Senas, Nyungwe is spoken by the Nyungwes, Emakhua (Makhua) is spoken by the Makhuas, etc.

At an administrative level, the country is made up of 10 provinces, from south to north: Maputo city, the capital, Maputo country, Gaza, Inhambane, Manica, Sofala, Zambezia, Tete, Nampula, Cabo Delgado, and Niassa. Mozambique's linguistic network (Figure 1) shows clearly that there is not one Bantu language that is spoken in all provinces, but rather languages belonging to the same group have a high degree of intelligibility to each other. Between different groups, however, this intelligibility diminishes drastically. This fact has three important implications.

1. Geographical variety plays a relevant role in successful communication between speakers.
2. It is difficult to determine when and if a dialect can be considered a language. Some linguists think that languages that are mutually intelligible are dialects from the group after which they are named; others, despite that intelligibility, consider them to be independent languages. The Tsonga group, for instance, comprises Xironga, Xichangane, and Xitshwa; some consider these to be Tsonga dialects, whereas others consider them independent languages.
3. Internal migratory flows due primarily to the war, have given rise to intermediate languages, because displaced individuals had to communicate in an entirely new linguistic scenery (Figure 2).

The existence of this complex language network was one of the main reasons why FRELIMO (Front for the Liberation of Mozambique; in Portuguese, Frente de Libertação de Moçambique), even during Mozambique's national liberation armed struggle (1964–1974), defined the Portuguese language as the national unity language and the country's official and educational language, thus forestalling any eventual claims of a nationalistic character, because no national language would then meet with country-wide consent.

Data

Figure 1 reveals an unavoidable situation: the country is a rich land made up of different linguistic nations, whose culture and *modus vivendi* are equally dissimilar. Different studies suggest a clear divergence regarding the total number of idioms with language status spoken in the country. For example, Lopes (1994) suggested that there are 21 national languages. Table 2 shows 10 different categorizations of Mozambican national languages.

Figure 2 Internal migratory flows, due primarily to the war, have given rise to intermediate languages.

Unfortunately, it is not possible to create a full description of Mozambican languages at the morpho-syntactic and phonological level in the present text because of the lack of reference grammars in these languages. The fullness and richness of their phonological aspects cannot as yet be shown because there are still no consensual phonetic representations of those languages. Instead, this article presents a general structural description of sentences.

A Mozambican Bantu sentence, as a rule, has the following basic order: (DP1-Subject + V + DP2/3 + Oblique(s)). Sentences are mostly SVO and have symmetric objects.

Table 2 Mozambican languages

Author	*Mozambican languages*

Electoral Process (1993)	Cicopi, Cimanyika, Cindau, Cinyanja, Cinyungwe, Cisena, Ciwutewe, Ciyao, Echuwabo, Elomwe, Emakhuwa, Emeeto, Gitonga, Kiswahili, Shimakonde, Xichangana, Xirhonga, Citshwa
Firmino and Machungo (1994)	Cibarwe, Cicopi, Cikunda, Cinyanja, Cinyungwe, Cisena, Cishona, Ciyao, Echuwabo, Ekoti, Elomwe, Emakhuwa, Gitonga, Kimwani, Nsenga, Shimakonde, Xichangana, Xirhonga, Citshwa
Lopes (1994)	Cicopi, Cinyanja, Cinyungwe, Cisena, Cisenga, Cishona, Ciyao, Echuwabo, Ekoti, Elomwe, Emakhuwa, Gitonga, Isizulu, Kimwani, Kiswahili, Memane, Shimakonde, Siswati, Xirhonga, Xitsonga, Citshwa
NELIMO (2000)[a]	Grupo I (Kimwani, Shimakonde, Ciyao) Grupo II (Emakhuwa, Echuwabu) Grupo III (Cinyanja, Cinyungwe, Cisena, Cibalke) Grupo IV (Cimanyika, Cindau, Ciutee) Grupo V (Gitonga, Cicopi) Grupo VI (Xichangana, Citshwa, Xirhonga)

[a]The orthography and phonetics of languages in NELIMO (1989) and (2000) are currently being studied.

The form structure of sentences occurs mainly in a post-verbal context in such constructions as (DP1-Subject + V + DP2 + DP3 ...). The selected structure has a double object, and the object sequence is ruled by such criteria as animacity degree, class of the involved DPs, symmetry/asymmetry, and the presence or absence of applicative, causative, and other morphemes. However, the disposition of objects can also be (DP1 + V + DP3 + DP2), as if, for example, it would be possible to say in English *John sent a letter Mary*. This structure causes serious problems to those speakers of a Bantu language as a first language who learn Portuguese as a second language. When imposing their first language structure onto Portuguese (their second language), they create atypical sentences according to European Portuguese syntax.

Current Bantu language studies are examining other grammatical components, as well as how Bantu language structures are imposed over Portuguese language and vice versa. This systematic and deepened study of Mozambican languages will lead to the consequent building of reliable grammars.

Current Status

Despite the current situation, recent studies point toward a promising future for the Mozambican languages. In the first *Seminar on the Standardization of Mozambican Languages Orthography* (1989) promoted by NELIMO (Eduardo Mondlane University), 20 Mozambican languages were identified. However, only 13 of those were submitted to an exploratory study.

Fifteen years after this important meeting and after the completion of several intermediate studies, NELIMO (2000) undertook the description of phonetics and the preparation of an orthography for 17 languages. The creation of consensual and definite orthographic systems is the first step toward preserving national languages. This may be a Herculean job, if we consider that the country's priorities also include eradicating poverty and epidemics while stabilizing a still young democracy.

Although the task of rehabilitating and regaining the national languages' prestige belongs to Mozambicans, the role played by the colonizing nation in the destruction of Mozambican's linguistic tissue remains the worst of all evils. The fact that Portugal has not yet defined a consistent linguistic policy and has no center of Bantu linguistics or a university that teaches structured classes of idioms from African Countries of Official Portuguese Languages (PALOP) aggravates the situation. Portuguese institutions still follow the New State policy by not investing in this area, despite Bantu languages' hegemony in the significant African underworld existing in ghettos surrounding great cities. Such neglect is in sharp contrast with the example given by such countries as Germany, the

Netherlands, Poland, Sweden, among others who have invested in Africa, despite the fact that they were former colonizers. In the United States, the United Kingdom, and France, teaching and research on the area of Bantu Linguistics are supported by acknowledged centers.

Conclusion

The historical experience of Portuguese colonization, its epidemics, natural disasters, scanty economic resources, three decades of war that tore apart the country, and the subsequent lack of public investment in education have left indelible marks on Mozambicans, the educational network, and the linguistic network. In spite of all that, Mozambican institutions and nongovernmental organizations directed at the study and systematization of Mozambique Bantu languages have increased their efforts, which are already bearing fruit. According to INDE (National Institute of Educational Development; in Portuguese, Instituto Nacional do Desenvolvimento da Educação) data, the teaching of national languages is taking place in several schools in different provinces, and official speech instigates the process, both of which point to an encouraging though still uncertain future.

Mufwene, Salikoko (b. 1947)

M Brdar, University of Osijek, Osijek, Croatia

© 2006 Elsevier Ltd. All rights reserved.

Salikoko S. Mufwene, an expert on creoles and pidgins, was born on November 1, 1947, in Mbaya-Lareme (Democratic Republic of Congo). The multilingualism of this environment was one the decisive factors that steered him toward a linguistic career. He graduated with highest honors in 1973 from the National University of Zaire at Lubumbashi, having majored in English philology. Thanks to a Fulbright scholarship, he was able to continue postgraduate studies in linguistics at the University of Chicago, completing his Ph.D. in 1979 with distinction. His doctoral dissertation, 'Semantic field' vs. 'semantic

class,' was supervised by James D. McCawley. His first job (January 1980 to August 1981) at the University of the West Indies in Mona, Jamaica, reoriented his interest in the syntax and semantics of creoles, particularly those of Jamaica and Guyana. He joined the University of Georgia at Athens as an assistant professor in September 1981, to be appointed associate professor in 1986 and full professor in 1991. The years in Athens (until December 1991) played an important role in his intellectual growth as a linguist and a creolist. This is where his personal linguistic background, linguistic training, and experience cumulatively came to full fruition. He returned to Chicago University in December 1991. From 1995 to 2001, he was chair of linguistics at the University of Chicago. He is now the Frank J. McLorraine Distinguished Service Professor of Linguistics.

Mufwene's research is informed by diverse sources, such as population genetics, macroecology, complexity theory, and globalization, as is evident from the way he applied ideas of multiple causation and non (uni)linear evolution to language phenomena in his most recent book, *The ecology of language evolution* (2001).

Ever since he became interested in creoles, he has studied morphosyntactic and semantic characteristics of Gullah, African–American Vernacular English, and Guyanese and Jamaican Creole. Around the mid-1980s, the development of his interests toward more general perspectives and theories became obvious as his focus widened from the development of 'Atlantic creoles' to varieties such as Kikongo-Kituba, Lingala, and North American English varieties, leading him in recent years to defend uniformitarianism. He raises a host of issues about the traditional practice of genetic linguistics. According to him, creoles have developed by the same restructuring processes that are observable in other languages; they remind us of the relevance of several factors, such as the dynamics of population contact and mutual accommodation, that have typically been downplayed. He questions the linguistic justification of the distinction between internally and externally motivated change, challenging genetic linguists to explain in which way creoles cannot be classified genetically.

Mukařovský, Jan (1891–1975)

M Hirschova, Palacky University Olomouc, Olomouc, Czech Republic

© 2006 Elsevier Ltd. All rights reserved.

Jan Mukařovský was born in the ancient city of Písek, Southern Bohemia. In 1915, he graduated with a degree in linguistics and aesthetics from the Charles University, Prague. After several years of teaching at Prague grammar schools, he became Professor of Aesthetics at Charles University in 1929. Since the early 1920s, he maintained contact with Roman Jakobson as well as with the group of Czech avant-garde authors V. Nezval, V. Vancura, K. Teige, and so on. Beginning in 1926, he participated at the informal meetings of a group of linguists and philologists sharing the ideas of functional structuralism. (His first lecture, given to the club in 1927, was titled 'On the motoric moves in poetry.') In October 1930, the informal group became an official association, the Prague Linguistic Circle (PLC), and Mukařovský was one of the 17 people who signed the foundation chart.

Mukařovský's first articles dealt with literary critics, but soon he turned to theoretical poetics, specifically the phonic and syllabic structure of verse. Influenced by the Russian Formal School of poetics, and by Jakobson's treatise *Foundations of the Czech verse*, Mukařovský developed an analysis of poetic language focusing on a language (linguistic) form of a literary utterance (text), on its sound patterning, its semantic organization, and its thematic structure. His analyses of Czech authors such as Mácha and

class,' was supervised by James D. McCawley. His first job (January 1980 to August 1981) at the University of the West Indies in Mona, Jamaica, reoriented his interest in the syntax and semantics of creoles, particularly those of Jamaica and Guyana. He joined the University of Georgia at Athens as an assistant professor in September 1981, to be appointed associate professor in 1986 and full professor in 1991. In October 1930, the informal group became an official association, the Prague Linguistic Circle (PLC), and Mukařovský was one of the 17 people who signed the foundation chart.

Mukařovský's first articles dealt with literary critics, but soon he turned to theoretical poetics, specifically the phonic and syllabic structure of verse. Influenced by the Russian Formal School of poetics, and by Jakobson's treatise *Foundations of the Czech verse*, Mukařovský developed an analysis of poetic language focusing on a language (linguistic) form of a literary utterance (text), on its sound patterning, its semantic organization, and its thematic structure. His analyses of Czech authors such as Mácha and

Němcová combine the abstract poetics of universal categories with an analytical poetics of individual literary works. The concentration on the formal features of literary texts brought Mukařovský to elaboration of a theoretical concept of a poetic language as opposed to the 'standard language' used in other fields of communication (cf. Jakobson's 'poetic function'). The most prominent feature of poetic language presented and studied in Mukařovský's articles and treatises since the early 1930s is the emphasis on the (language) form in which the content is being conveyed. A poetic language accentuates itself, drawing attention primarily to the deliberately foregrounded form (Mukařovský's term is *aktualisace*) of the message. The aesthetic values of a literary (poetic) work consist in the unusualness and uniqueness, in the maximum of formal disautomatization ('aesthetically purposeful distortion') of the articulated meaning. In different degrees, poetic language deliberately breaks the rules of grammar; wherever poetic function is dominant, the language represents itself first, and only secondarily it refers to the reality. It does not mean that poetic language is entirely independent of the other language functions. All signs, including aesthetic signs, fulfill certain needs of their users. As Mukařovský wrote, every concept is determined by all the others and in turn determines them; thus, a concept is defined unequivocally by the place it occupies in a conceptual system. Therefore, even aesthetics and poetics are interdisciplinary fields; they should not lose touch with the advancement of human and social sciences. Later, Mukařovský proposed and explored the concept of semantic gesture, a poet's idiosyncratic 'constructional principle,' which is applied in every segment of the work, even the most minute, and which results in a unified and unifying systematization of all the constituents. Both in its name and in its sense, semantic gesture ties the literary structure to the creative subject; the organizational principle of the work's semantics has a pragmatic base. Mukařovský's considerable pragmatic inspiration by dramatic arts and presentation of poetry are reflected in his often quoted study, *Dialogue and monologue* (1940). Mukařovský's most important theoretical and analytical studies were published in 1948. His concept of poetic language is still influential in the literary semiotics.

After World War II, PLC activities were resumed only on a limited basis since some of the prominent members had died (Trubeckoj and Mathesius), and others did not return from exile (Jakobson and Wellek). Soon (especially after February 1948), the theoretical principles of PLC, as well as structuralism in general, became ideologically unacceptable for the new communist regime in Czechoslovakia, and the PLC ceased to exist. Unlike most of the other former PLC members, Mukařovský, obviously due to his prewar contacts with left-wing authors and artists, did not have a problem to embrace the Marxist ideology and political requirements of the new communist government. He became a rector (president) of Charles University in the years in which political pressure affected the Czech academic environment (1948–1953). Later he became head of the Academic Institute of the Czech Literature, established after a Soviet model (1951–1962). In his bibliography of 1947–1967, ideological and political articles are far more numerous than literary studies. Nevertheless, the influence of his earlier works has lasted.

Mulcaster, Richard (1532–1611)

J B Walmsley, Universität Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Richard Mulcaster was born in Cumbria, England, in 1531 or 1532. From Eton he went on to Cambridge in 1548, and from there to Oxford, where he took an M.A. in 1556. He then moved to London, and in 1581 was made head of the Merchant Taylors' School. From 1586 to 1596 he trained for the priesthood, but in 1596 was appointed to a post at St. Paul's School, resigning as High Master in 1608. He died on April 15, 1611.

Mulcaster's interest to historians of language and linguistics lies in his *Positions* (1581) and the *Elementarie* (1582). Mulcaster's purpose in the *Positions* was "to shew mine opinion how the great varietie in teaching which is now generally vsed, maye be reduced to some vniformnesse" (Mulcaster, 1581: 296). Dedicated to Queen Elizabeth I, *Positions* provided an outline for a comprehensive system of public education covering such topics as the role of languages in the curriculum, physical education, access to education, and readiness for learning.

The *Elementarie* addresses the problem of establishing a satisfactory system of spelling for English and constitutes the first survey of rules for English orthography. The heart of the work is "THE GENERALL TABLE" (1582: 170–225), which gives a list of English words in their recommended orthographies. In this work, Mulcaster advocated, first, adopting existing forms which came closest to a so-called 'phonemic' orthography (an argument from 'reason' – analogy) and second, allowing unphonetic spellings in common words sanctioned by custom (anomaly). Among the spelling reforms credited to Mulcaster are the reduction of final double consonants from two to one after a lax vowel (*put* and *grub*, for *putt* and *grubb*) and the regularizing of final *–e* as a sign of vowel quality (sometimes described as 'length') as in *name*. Mulcaster also corrected some false 'etymological' spellings such as *abominable* for *abhominable* (*ab* + *omen* for *ab* + *homo*).

Mulcaster assigned an innovative role to grammar in education: an English child should first acquire a reading knowledge of English, followed by a reading knowledge of Latin. After this, the grammar of the native language should be learned as a foundation for learning the grammar of Latin (Mulcaster, 1582: 55).

Mulcaster's proposals for orthographical reform stand in a line of development running from Smith (1568) and Hart (1569) – both more radical in their proposals than Mulcaster – to Coote (1596), Gil (1619) (his successor at St. Paul's), and Butler (1633).

Mulcaster also constitutes an important touchstone in the history of English, marking shifts in the language ecology and changing attitudes to the vernacular. He believed that English had achieved its highest level of perfection and could stand comparison with any language: "I do not think that anie language . . . is better able to vtter all arguments, either with more pith, or greater pleasure, than our *English* tung is . . . " (Mulcaster, 1582: 258).

Mulder, Johannes W. Franciscus (b. 1919)

R Thelwall, Calgary, Alberta, Canada

© 2006 Elsevier Ltd. All rights reserved.

J. W. F. Mulder was born in Arnhem, the Netherlands on June 28, 1919. After an interrupted education and anti-Nazi activities during World War II, he found himself in Indonesia at independence, having picked up some Chinese, Sundanese, and Korean. He completed 2 years at the reopened University of Djakarta. On returning to the Netherlands, he was allowed to matriculate at the University of Leiden after impressing a panel, including Uhlenbeck, with his linguistic skills. His talents as a polyglot were now to be extended to theoretical linguistics to satisfy his need for data description. He was fortunate in the active group of linguists in Leiden, who also participated in contacts with the descendants of the Prague School and Martinet's emerging Paris school. These various elements included a keen interest in the philosophy of science, logic, and mathematical techniques alongside a practical knowledge of an impressive array of world languages. In such circles, analytical proposals were immediately tested across a wide range of languages.

Mulder completed his doctorate at Leiden in 1958 on Chinese. In 1961, he became Far Eastern librarian at the Oriental Institute in Oxford. Finding that his preceding degrees were not recognized, he set about presenting a D.Phil. under the supervision of David Hawkes, Professor of Chinese. This was subsequently published in revised form as *Sets and relations in phonology: an axiomatic approach* (1968, Clarendon). During this period, he also lectured in linguistics at Oxford (when there was no formally constituted linguistics program) and became the guiding light of a group of students (studying Chinese or Japanese) who were to provide the base for the implementation of his strategic linguistic vision.

In 1968, he was appointed Senior Lecturer in Linguistics at St. Andrews University and set about turning one post into a department. In an era of generative dominance, to create a new theoretical base and then apply it via descriptions of a wide variety of linguistic phenomena (as well as to semiology) might seem verging on the hubristic. Fortunately for us, pluralism still finds its niches.

With the appointment of Sandor Hervey, one of the Oxford bunch – and the openness to his ideas provided by the Martinet network (including the journal *La Linguistique*) and the LACUS forum, Sidney Lamb and other colleagues in the US and Canada – they set about teaching, writing, and supervising M.A. and Ph.D. theses to expand their field. In 1980, *The strategy of linguistics* was published with Hervey. By this time, his theory was graced with a name: Axiomatic Functionalism (or AF). Hervey's own Ph.D. on semantics appeared in 1979. Mulder has been involved with the Société Internationale de Linguistique Fonctionnelle (SIL) since its inception in the early 1970s and has been its honorary president for some years. Mulder, now based in Belgium, is still actively researching and publishing.

Müller, Friedrich Max (1823–1900)

P C Sutcliffe, Colgate University, Hamilton, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Friedrich Max Müller was a comparative philologist and Sanskritist at Oxford who presented public lectures on the science of language. These made him very famous in his lifetime, but he is also often (though controversially) considered a founder of comparative mythology and comparative religion. Largely forgotten after his death, his reputation is now making a comeback to the extent that his historical importance is understood beyond the boundaries of linguistics.

Born in Dessau on December 6, 1823, Müller was the son of the poet Wilhelm Müller, most famous for Schubert's musical setting of two poems, 'Die schöne Müllerin' and 'Winterreise.' In 1841, Müller began studying classical languages and also Oriental

languages and Sanskrit with Brockhaus, as well as philosophy at the University of Leipzig. After receiving his Ph.D. in 1843, he studied comparative philology and Sanskrit with Franz Bopp, and philosophy with Schelling in Berlin for one year. In 1845, he studied in Paris with Eugène Burnouf and was influenced by his racial theories of comparative religion. Burnouf also encouraged Müller to translate the *Rig-Veda*, a project which took Müller to England in 1846 and 1847, where manuscripts were located in the library of the East India Company in London. With the patronage of German Ambassador Baron Bunsen, Müller was able to convince the Company to publish his translation with Sayana's commentary. To supervise the publication, Müller went to Oxford in 1848, where he remained until his death on October 28, 1900.

At Oxford, Müller took over the Taylorian Professorship of Modern Languages in 1851 when its holder became ill, and he was officially appointed in 1854. In 1860, Müller was passed over for the Boden Chair of Sanskrit at Oxford in favor of M. Monier-Williams, because Colonel Boden's intentions with the founding of the Chair were primarily missionary. In 1868, Oxford established a Chair of Comparative Philology for Müller, a position he held until he retired in 1876.

Müller was a very prolific scholar, whose oeuvre comprises many thousands of pages, and whose interests ranged from political uses of linguistics (e.g., *Suggestions for the assistance of officers in learning the languages of the seat of war in the east*, 1854) to comparative religion and mythology (e.g., *Introduction to the science of religion*, 1873), and philosophy (he translated Kant's *Critique of pure reason* in 1881). His most important contributions to Sanskrit studies are his 6-volume *Rig-Veda* translation (1849–1874) and his *Sanskrit grammar for beginners* (1866). In comparative religion, his most lasting contribution was inaugurating and editing the *Sacred Books of the East*, a series of 50 translations of religious texts deemed canonical in their communities, some of which he translated himself (including *Upanishads* Pts. 1 and 2, 1879–1884, and *Vedic Hymns*, Pt. 1, 1891). Without these translations, the comparative study of religions would not have been possible.

In comparative philology, Müller is best remembered for his *Lectures on the science of language* (1865), which were delivered at the Royal Institution in London in 1861 and 1863 and attended by notables such as Queen Victoria and J. S. Mill. With these lectures, Müller popularized "the science of language" by emphasizing its relevance to all human knowledge, based in his understanding of the "identity" of language and thought. With this phrase, Müller was echoing a Humboldtian notion that language and thought were interdependent processes (see Sutcliffe, 2001: 26). This claim also provided the foundation for Müller's refutation of Darwin's theory of evolution as applied to man. (Darwin had asked Müller to provide his expert opinion.) For Müller, because language and thought were 'identical' or interdependent, both had to be present from the beginning – language could not have evolved gradually because that would imply that thought could have existed independently of language. The roots of language as exemplified by the roots of Sanskrit thus represent the fundamental concepts, the roots of human thought, to him. On the other hand, prefiguring the Neogrammarians, Müller posited two principles of language change, phonetic decay and dialectal variation, to explain its regularity. Müller even classified the science of language as a physical, rather than a human, science because of the law-bound behavior of languages.

It was probably Müller's extremely broad range and popularity that led to the swift decline of his reputation after his death. He had a number of critics among linguists who considered him superficial, among them William Dwight Whitney, who devoted a book to discrediting Müller's theory (Whitney, 1892). Also, with the advent of Saussurean structuralism and its concomitant scientific specialization, the importance of comparative philology and of humanist scholars like Müller diminished. Van den Bosch located Müller's most lasting legacy in comparative religion and mythology, where Müller influenced H. Usener, who in turn influenced E. Cassirer (Van den Bosch, 2002: 523). Yet Müller's analysis of religion and mythology was grounded in his linguistics, utilizing etymological analysis of gods' names to conclude that mythology arose from a "disease of language", a property inherent in it causing ancient peoples to interpret metaphors to explain natural phenomena literally. As Müller himself wrote, the thread connecting all of his labors also connected "the origin of thought and language with the origin of mythology and religion" (Müller, 1901: 3).

Multiculturalism and Language

J R Edwards

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the Concise Encyclopedia of Sociolinguistics, pp. 48–50, © 2001, Elsevier Ltd.

Focusing upon linguistic and cultural contact means focusing upon group identity. It is this sense of 'groupness' – ethnic or national – and the recognition that both underpins and reflects it, that constitute the core of the discussion on multiculturalism, a discourse that is essentially sociopsychological and usually emotionally charged. This can be true from either side of group boundaries: linguistic and cultural continuity, for example, can be both a rallying point for members of a beleaguered minority and an irritant (or worse) for those fearful of social balkanization or fissiparous movements. Multiculturalism is an icon for some, an illusion for others. And language – particularly in its symbolic roles, as well as in those communicative ones that link past to present, that bear culture across generations – is in many instances the centerpiece of the multicultural thrust. During and after language shift, it is certainly possible to maintain cultural distinctiveness and the sense of border that is the heart of group definition. However, this is not a viewpoint likely to be endorsed by people who feel themselves at risk of assimilation, nor can it be denied that continuity of language use is a powerful cultural buttress.

The politics of identity – the skeleton, that is to say, which is fleshed out by cultural and linguistic differences, details, and demands – is of special current salience. Our age is one of transition, and transitions are often difficult and painful. In the territories of the former Soviet Union, in the increasing western European federalism, in the killing fields of Africa – but also in the struggles of indigenous peoples in North and South America, in the debates on multicultural accommodations in new-world 'receiving' societies (Canada, Australia, the United States) – we see contexts in flux, identities up for renegotiation, languages in contact or conflict, 'small' cultures attempting to resist larger ones, and so on. It is true that, in some cases, the 'ethnic' factor in conflict is something of a red herring. The Hutus and the Tutsis of Rwanda essentially share the same culture, religion, and language and, consequently, ethnic difference was not the real nub of the conflict that led to the massacres in 1994. In Africa, Asia, and elsewhere, colonialism planted many delayed-action devices, emphasizing and stiffening cultural difference. But even if ethnic or nationalist roots are not, in themselves, causal phenomena (in situations of group friction), their very existence – the fact that they are *there*, the fact that dormant, or even unreal, traditions can be evoked and played upon, the fact that manipulated or selective history can be made to serve current ends – is of considerable importance. In some other cases, matters of language and culture are not only symbolic markers signaling deeper waters, but are more centrally implicated in intergroup conflict. It is not economic deprivation or lack of effective political representation in federal corridors that primarily fuels the sovereignty movement in Quebec – yet its power has come within a hair's breadth of breaking up the country.

Multiculturalism usually implies multilingualism and, at a *de facto* level, they exist in virtually all

It is not economic deprivation or lack of effective political representation in federal corridors that primarily fuels the sovereignty movement in Quebec – yet its power has come within a hair's breadth of breaking up the country.

Multiculturalism usually implies multilingualism and, at a *de facto* level, they exist in virtually all

countries, in very few of which national and state borders are coterminous (see Connor, 1978). At a *de jure* level, languages are more often accommodated than are cultures. Still, despite a large number of languages and a small number of states – about 5000 and 200, respectively – only about a quarter of the world's polities recognize more than one language (and recognition itself rarely implies or reflects equivalent status; see Edwards, 1995).

Legislated attention to cultural diversity is rare, and Canada and Australia are virtually alone in having official multicultural policies. The Canadian approach is generally illustrative. Two years after the establishment of linguistic duality (with the Official Languages Act of 1969), a policy of multiculturalism was announced, and an Act was passed in 1988 – the aims were, from the first, to assist cultural groups to develop and to contribute to the larger society, and to help them learn either or both of the two official languages. Further elaboration (as found in the Act) stressed the preservation and enhancement of other languages – but this is supposed to coincide with the strengthening of English and French, too, the national commitment to which is reaffirmed. The Canadian policy demonstrates, then, the generalities employed when cultural maintenance or the continuity of non-official languages is under discussion (the Act talks of enhancing the Canadian 'multicultural heritage'), as opposed to the specificity attaching to the status of legally sanctioned varieties. Unsurprisingly, this package has been seen as rather an empty one; more pointedly, the feasibility of **multi**culturalism within a **bil**ingual framework and the depth, therefore, of real government commitment has been questioned. Of course, reactions to official multiculturalism range very widely, from the mistaken notion that it is a spur to ethnic separatism and an impediment to national unity (perhaps, indeed, to the emergence of some eventual, nonhyphenated **Canadian** identity), to the naïve belief that it enshrines and reflects a general tolerance for diversity – evidence for the moral superiority of the Canadian 'mosaic' over the more southerly 'melting pot.'

But the Canadian policy, for all its generality and its possible interpretations, is more broadly significant as an example of political response to diversity. Liberal democracies are of course obliged by deepest principle to consider multicultural realities – but consideration does not imply uniformity of sensitivity or reaction. In the Canadian approach to multiculturalism, an apparent response at the level of the group, the collectivity, is arguably of such a general nature (and, one should add, is so weakly supported, financially and otherwise) that it represents only a tiny course adjustment to the more traditional liberal stance in which rights are seen to inhere in individuals, a stance broadly descriptive of contemporary Western society. So, to the reactions already mentioned, we can add two further interpretations of multicultural policy: it represents only politically opportunistic lip service to the idea of cultural maintenance (a view which could of course be **endorsed** by the cynical assimilationist); or, it is a genuine response to heterogeneity, but one that is unfortunately flawed in its framing and its application. It need hardly be said that these and other stances are not unique to the Canadian context.

The appropriate democratic response to cultural diversity is of course the underlying issue here. Should there be formal multicultural policies at all and, if so, should they enshrine some level of commitment to group rights? What level? And what groups? The literature on multiculturalism and its ramifications – pluralist accommodation, the negotiation of identity, the rights of minorities, the obligations of the liberal state, and so on – has only recently turned to such matters. The turn, however, has been significant, and there is now a concern for 'identity' that extends from literature, to the social and political sciences, to philosophy.

In his treatment of 'identity politics,' Taylor invokes the idea of 'recognition' and, more specifically, the politics of equal recognition as fundamental. But this can shade easily into a politics of group difference, in which the uniqueness of group identity is emphasized. It is this, of course, that adherents claim is at risk of being ignored or, worse, assimilated to some overarching majority (the "cardinal sin against the ideal of authenticity": Taylor, 1994: 38). So we arrive at an interesting juncture: the principle of universal equality is stressed but within that, as it were, arise demands for the recognition of distinctiveness. The demands of general respect, on the one hand, and of particularity, on the other, lead to difficulties:

> The reproach the first makes to the second is just that it violates the principle of nondiscrimination. The reproach the second makes to the first is that it negates identity by forcing people into a homogeneous mold that is untrue to them. (Taylor, 1994: 43)

Bearing in mind the traditional liberal sense that society ought to ensure individual equality but remain neutral as to the desired contents of lives, but aware of the concerns of cultural collectivities (especially, of course, those under threat from powerful neighbors), Taylor argues for a more 'hospitable' liberalism that departs somewhat from this traditional neutrality, for the idea that cultures should be given some means of self-defense, for at least an initial presumption of equal worth – for something, that is, between

a cruel homogenization and an ethnocentric self-immurement.

Kymlicka (1995) has also addressed the matter, arguing that it is within the bounds of liberal democracy to provide groups with the means to ensure their cultural continuity – and, where these groups are specially disadvantaged, this may in turn require special attention, perhaps special rights. In this connection, he defends treatment differentiating between indigenous minorities and immigrant groups. Kymlicka (see also 1998) has concerned himself particularly with the Canadian context, suggesting that the multicultural policy is – or could be – an effective instrument. It is interesting (given what I have noted above) that he repeatedly points out that this policy, now to be understood as a vehicle for the provision of group rights, is, after all, no real threat to the *status quo*. Diversity will be subject to reasonable limits, and existing conceptions of rights, freedoms, and human dignity will not be overturned.

It is impossible to analyze here the rich detail of these sorts of arguments (or, indeed, to note the criticism they have elicited). But they are the ones we now need, since they confront the underpinnings of multiculturalism and may thus lead to useful generalities applicable across contexts. A great deal of the literature has, for too long, consisted of special pleading for one group or another, under the guise of a broad concern for pluralist accommodation. A more profound assessment of multiculturalism will necessarily involve its linguistic components, and that is why I have emphasized the former in this brief discussion. It is of course possible to attend to language *per se* without much concern for its cultural foundations. But an instrumental approach omits the essence of the matter here: the interweaving of language as a strand in the larger fabric, as part of a broad concern with identity and belonging.

Monolingual Perspective of Pragmatics Research

The study of pragmatics should answer two primary questions. From the perspective of production, the question is, why do we choose to say what we say? As far as comprehension is concerned, it is, why do we understand things the way we do? One of the major problems of pragmatics is that so far the only answers to these questions come from research that is heavily biased by monolingual approaches. When pragmaticians develop their theories, they usually do not think about people who speak more than one language. This has been a long-standing problem in pragmatics-oriented research. Communication is becoming more and more intercultural because it involves interactants who have different first languages, communicate in a common language, and represent different cultures. Pragmatics research, however, with the exception of interlanguage pragmatics, does not seem to pay much attention to intercultural communications and remains predominantly monolingual in scope. Major issues and theories of pragmatics are discussed in a monolingual framework that lacks or excludes any explanation of or reference to the applicability of ideas, theories, and research findings to bi- and multilingual settings.

Why is this narrow focus a problem? What is wrong with the monolingual view? The problem is that the most powerful theories of pragmatics, including the Gricean (1961) approach, Brown and Levinson's (1987) politeness theory, and Sperber and Wilson's relevance theory, presuppose that rules of communication, communicative principles, and interpretation and production processes are basically the same or very similar no matter what language we use. However, a close look at bi- and multilingual language production demonstrates that this is not exactly so.

Monolingual Perspective of Pragmatics Research

The study of pragmatics should answer two primary questions. From the perspective of production, the question is, why do we choose to say what we say? As far as comprehension is concerned, it is, why do we understand things the way we do? One of the major problems of pragmatics is that so far the only answers to these questions come from research that is heavily biased by monolingual approaches. When pragmaticians develop their theories, they usually do not think about people who speak more than one language. This has been a long-standing problem in pragmatics-oriented research. Communication is becoming more and more intercultural because it involves interactants who have different first languages, communicate in a common language, and represent different cultures. Pragmatics research, however, with the exception of interlanguage pragmatics, does not seem to pay much attention to intercultural communications and remains predominantly monolingual in scope. Major issues and theories of pragmatics are discussed in a monolingual framework that lacks or excludes any explanation of or reference to the applicability of ideas, theories, and research findings to bi- and multilingual settings.

Why is this narrow focus a problem? What is wrong with the monolingual view? The problem is that the most powerful theories of pragmatics, including the Gricean (1961) approach, Brown and Levinson's (1987) politeness theory, and Sperber and Wilson's relevance theory, presuppose that rules of communication, communicative principles, and interpretation and production processes are basically the same or very similar no matter what language we use. However, a close look at bi- and multilingual language production demonstrates that this is not exactly so.

Language Use of Multilinguals

Language use is governed not only by universal but also by language- and culture-specific rules. A person who speaks two or more languages may share universal rules with a monolingual speaker, but will have two different sets of culture-specific, language-community-specific rules. This will result in production in either language that is not exactly the same as the language production/use of a monolingual speaker of either language. A bilingual is not two monolinguals in one body (Grosjean, 1985). Bi- and multilingualism are characterized by a unique synergism of more than one language and culture that significantly affects how bi- and multilinguals use language (Kecskes and Papp, 2000).

Pragmatics is about language use. Morris defined pragmatics as "the study of the relation of signs to interpreters" (Morris, 1938: 6). Ever since, all definitions of pragmatics have derived from his, trying to make it more specific. The participants in the 'game' that we call communication are the same in all definitions: the linguistic code, the interpreters of the code, and the linguistic and extralinguistic context (frame) of interpretation. Communication is about the interplay of these three elements. No one denies that interpreters do similar things with the code, no matter what language(s) they speak.

Consequently, the real issue for those investigating bi- and multilingual language use is not *what* is done with the code, but rather *how* it is done. Monolingual people and bilingual people do not differ in what they do with language, but in how they do what they do. There are similarities and differences between the language use of monolingual people and of bi- or multilingual people. The differences are usually manifested in such phenomena as code switching, different interpretation of one and the same thing, misunderstandings, different values, and approaches. What interests us here is why and how the same code is used differently by three groups of people: (1) monolinguals speaking that code as their L1; (2) bi- or multilinguals using that code as their L1, but having access to other language channels in their mind; and (3) bi- or multilinguals who do not have the language of interaction as their L1, but as their L2 (or Ln). Researchers working in two subfields of pragmatics – interlanguage pragmatics and cross-cultural pragmatics – have attempted to answer this question (*see* **Intercultural Pragmatics and Communication**.

Interlanguage Pragmatics

In the last two decades, interlanguage pragmatics has grown as a discipline that has been engaged in research in L2 learner language. This branch of pragmatics discusses how nonnative speakers comprehend and produce a speech act in a target language and how their pragmatic competence develops over time (e.g., Kasper and Blum-Kulka, 1993; Kasper, 1996). To date, many cross-sectional, longitudinal, and theoretical studies have been conducted mainly on a classroom basis, which has resulted in a special tie between interlanguage pragmatics and second language acquisition research.

Interlanguage pragmatics is based primarily on three theoretical constructs: the Gricean (1961) theory of pragmatics, Brown and Levinson's (1987) view of politeness, and interlanguage theory. Recently, attempts have been made to integrate Relevance Theory (e.g., Escandell-Vidal, 1996; Jary, 1998) and Conversational Analysis (e.g., Kasper, 2004) into interlanguage pragmatics. The main areas of research in this paradigm are pragmatic competence, speech acts, politeness, and pragmatic transfer. The ability to comprehend and produce a communicative act is referred to as *pragmatic competence* (Paradis, 1998; Kasper, 1997). This ability usually is based on one's knowledge about social distance and social status between speakers, cultural knowledge such as politeness, and both explicit and implicit linguistic knowledge (*see* **Relevance Theory**; **Conversation Analysis**).

Interlanguage pragmatics often goes hand in hand with cross-cultural pragmatics, which emphasizes that pragmatic principles that people abide by in one language are often different in another language. There has recently been a growing interest in how people using different languages observe the same pragmatic principle. Cross-cultural studies focus mainly on speech-act realizations in different cultures, cultural breakdowns, pragmatic failure, and the way something that is considered polite in one language is sometimes considered impolite in another.

The problem with interlanguage pragmatics is that it represents a monolingual and cross-cultural rather than a multilingual and intercultural view because all of its theoretical resources (Gricean theory, politeness theory, and interlanguage theory) advocate the relative independence rather than interdependence of language systems and the universality of cooperative and politeness principles. Wierzbicka (1985), Goddard and Wierzbicka (1997), and Meier (1997) questioned the claims that emphasized the universality of Grice's Co-operative Principle and of Brown and Levinson's theory of politeness (Brown and Levinson, 1987). For instance, they made a case for the cultural relativity of definitions of sincerity and relevance in a given speech community, or the ranking of imposition when a request is made.

The interlanguage theory sets out to describe the developmental route of the new language from the moment it is still a subcategory of L1 until native-like competence is achieved. According to this approach, theoretically one person can have two language competencies, which contradicts the "a bilingual is not two monolinguals in one body" claim of Grosjean (1985). As a consequence of the two native-like competencies view, interlanguage theory supports crosscultural rather than intercultural pragmatics research. Although the terms 'intercultural' and 'cross-cultural' are often used interchangeably, they do not have the same meaning. Cross-cultural communication is usually considered to be the study of a particular idea(s) or concept(s) within several cultures that compares one culture to another on the aspect of interest, whereas intercultural communication focuses on interactions among people from different cultures.

Another problem with the interlanguage theory is that it focuses on linguistic and sociocultural aspects of language development and use while ignoring almost completely its cognitive, conceptual aspects. The cognitive aspect is present in the account of mental representation of the linguistic system.

Interlanguage theory is about the emerging second language, rather than a unique symbiosis of two languages, a dual language, which is affected by the dynamic nature and bidirectionality of transfer, as well as conceptual blending. The final goal of interlanguage development is native-like competence, which is possible only if we accept that a new conceptual system emerges to operate the new language system, and switching between two languages presupposes switching between two conceptual systems. This, however, contradicts recent findings in bi- and multilingual research where there is a strong claim for a common underlying conceptual system (e.g., Paradis, 1995; Kecskes and Papp, 2000).

Dual Language Theory

The dual language theory has been put forward as an alternative to interlanguage theory (Kecskes and Papp, 2000; Kecskes, 2003). 'Inter' means 'in between.' However, the language learner is not in between something, but rather is in the process of changing the existing conceptual and linguistic system by adding new information that will result in a qualitative change in the conceptual system and the emergence of a new linguistic system rooted in one and the same conceptual system. The dual language theory (DLT) is an 'intake' rather than an 'input' approach because it emphasizes the conceptual system and investigates what happens to the knowledge that enters the Common Underlying Conceptual Base (CUCB) through the two or more language channels, as well as how this knowledge is used through the language channels.

Rather than focusing on the target language features, the DLT points to the process of language construction itself, conceptual change, bidirectional influence, and movements not only up but also down on the developmental continuum. The languages are kept separate, but thoughts originating from the same conceptual system can be fed into two language channels. This fact has a profound impact on pragmatic skills and performance: what we choose to say, how we choose to say something, how we understand things said to us, and what we consider relevant. Consequently, the DLT can serve as a theoretical foundation for bi- and multilingual pragmatics. From a perspective of the extent of the interdependence of two or more languages in the dual or multilingual system, the DLT differentiates two main developmental periods: transfer period and conceptual change period (Kecskes and Papp, 2000; Kecskes, 2004).

Language Transfer

The first phase of bi- and multilingual development is dominated by unidirectional (L1→L2) processes and the production of the individual learner's elements. Transfer in the opposite direction (L2→L1) is not significant. In this period, the L1 is usually flexible enough to add the emerging second language as an additional register to those already in existence (De Bot, 1992). Transfer in this phase seems to be a matter of interaction of the language channels, rather than the conceptual system. Consequently, this transfer is usually considered to be a negative phenomenon that is generally the sign of the lack of some kind of linguistic and/or pragmatic knowledge and that takes the form of grammatical and/or lexical mistakes and errors. In this period, the main issue is correctness, rather than appropriateness.

Conceptual Change

The second developmental period begins when the conceptual system of the learner is affected by the knowledge and new information that come through the emerging new language channel. This phase is characterized by bidirectional influence and by changes both in the linguistic and conceptual system. The more proficient the learner becomes in the L2, and the more firmly the CUCB is established in the mind, the more positive is the result of bidirectional influence. This period is dominated by qualitative conceptual change that makes it possible to use knowledge and skills gained through either

language channel in both monolingual and bilingual language modes. This has a serious bearing on the learner's language behavior and discourse organization, which may be characterized in this period by switches between codes, depending on communicative needs. This phenomenon hardly resembles what we call 'transfer' in the first period. It is 'blending.' rather than transfer: conceptual blending of knowledge and information that come through either language channel. The result is positive rather than negative and originates in the changing and dynamic nature of bidirectional movements in the dual language system.

Inferencing in the Multilingual Mind

According to Grice (1961), the decisive feature of pragmatic interpretation is its 'inferential' nature. He argued that most aspects of utterance interpretation that traditionally are regarded as conventional, or semantic, should be treated as conversational, or pragmatic. This means that the hearer constructs and evaluates a hypothesis about the speaker's meaning. In this process, the hearer relies on three factors: the meaning of utterances, contextual and background assumptions, and general communicative principles that speakers are supposed to observe in normal circumstances. The question is how these three factors affect the process of inferencing in the case of multilinguals.

In the language transfer phase of dual language or multilanguage development, pragmatic failures in production and comprehension are mainly caused by the low proficiency level of learners and the strong dominance of the L1-based conceptual system that determines the communicative behavior of learners. The conceptual change period, however, is entirely different. Linguistic problems decrease while acculturation issues come to the fore. An advanced nonnative speaker cannot be expected "simply to abandon his/her own cultural world" (Barro *et al.*, 1993: 56). Adamson (1988) also pointed out that nonnative speakers are often reluctant to accept and share the values, beliefs, and presuppositions of an L2 community, even if they have been living there for a long period of time and can speak the language quite well. Kecskes and Papp (2000) argued that students seem to have more control over their pragmatic development than their grammatical development. They frequently learn pragmatic units and develop pragmatic attitudes by choice, which they usually cannot do when learning grammar. This is why speakers with high grammatical proficiency will not necessarily show concomitant pragmatic skills. Bardovi-Harlig (1996) observed that the range of success among students with a high level of grammatical proficiency is quite wide. Successfully reaching the acculturation threshold depends not only on the development of L2 language proficiency but also on the willingness of the speaker to acquire new sociocultural frameworks and make them a functional part of his or her CUCB.

Conceptual blending in the CUCB may result in a pragmatic style that does not exactly match that of either language. Rather, this style is a unique synergic mode of communicative behavior that is the result of conceptual blending. Blum-Kulka and Kasper (1993) discussed a similar phenomenon in their intercultural style hypothesis. They argued that speakers who are fully competent in two languages may create an intercultural style of speaking that is both related to and distinct from the styles prevalent in the two substrata, a style on which they rely, regardless of the language being used. This claim is supported by several studies of crosscultural communication, especially those focusing on interactional sociolinguistics (e.g., Gumperz, 1982; Tannen, 1985) and the pragmatic behavior of immigrant populations across generations (e.g., Clyne *et al.*, 1991).

Conclusion

Pragmatics research has two important tasks: (1) to develop a theory (or theories) that can explain not only monolingual but also multilingual language use and discourse, and (2) to revise our existing knowledge about the emergence of subsequent languages and their effect on the conceptual system of learners. In this endeavor, special attention must be paid to the analysis of real-life conversations between speakers who have different first languages, use a common language, and represent different cultures. Bi- and multilingual pragmatics requires that our perspective on language use be not only cross-cultural but also intercultural, where the focus is on interactions among people from different cultures, rather than on a comparison of interactions among people from the same culture to those from another.

Multimodal Interaction

Multimodal interaction involves a person's use of more than one of their natural communication modes, such as spoken language, gesture, sketch, writing, eye gaze, body posture, and so forth, to communicate with a partner. For a computer to respond appropriately, it will need to derive coherent communicative intent from this combined set of inputs. This article summarizes the advantages of multimodal interaction, progress in our understanding of humans' multimodal performance, the state of the art in multimodal system processing, and challenges and opportunities for future science and technology of multimodal interaction. This article does not cover multimodal presentation planning and output (e.g., generating utterances coupled with the graphical output).

Currently, the best developed multimodal systems process users' speech and touch- or pen-based inputs (e.g., sketch and/or handwriting) and audiovisual speech recognition. Multimodal systems frequently involve spatial applications, such as map-based planning (Cohen *et al.*, 1997; Johnston *et al.*, 1997; Oviatt and van Gent, 1996; Oviatt, 1997) and have been used to support information-seeking dialogues, for example, at public kiosks (Wahlster, 2001). Pen–voice multimodal systems enable users to refer to or describe objects, events, and relations, while processing gestures that depict spatial location, shape, number, motion, or other object or action modifiers. Audiovisual speech recognition systems recognize speech by combining both acoustic and visual information (e.g., from lip movements). Potamianos *et al.* (2004) provide an excellent introduction to the state of the art in this area.

Research is progressing on other modality combinations. Inspired by Bolt's (1980) seminal Put-that-there system, there have been numerous systems that process both users' speech and arm or hand gestures, often for virtual reality applications (Kaiser *et al.*, 2003; Pavlovic *et al.*, 1997; Richard *et al.*, 1996; Latoschik, 2002) or robot control (Perzanowski *et al.*, 2001). Some multimodal systems also incorporate information about what is in the user's field of view (Kaiser *et al.*, 2003). Finally, eye gaze is rapidly becoming a tool that can be used in multimodal systems, with systems having been built that combine eye gaze with manual input or speech (Koons *et al.*, 1993; Zhai *et al.*, 1999). Other research is working toward combining information on gaze movements with task-oriented spoken dialogue (Qvarfordt, 2004).

These modalities are especially suited to nontraditional computing environments, i.e., those that are off the desktop, such as mobile usage, both pedestrian and in-vehicle (Potamianos and Neti, 2003). In these environments, multimodal interaction will be particularly advantageous both for small devices (cell phone, PDA (Kumar *et al.*, 2004), and digital paper (Cohen and McGee, 2004)) and for large ones (data walls) as well as computing environments for which the user is not intended to conceive of a device *per se*, such as so-called 'ubiquitous computing' or 'smart' environments. In all these environments, the user is always equipped with their natural modes of communication – speech and body movement, as well as use of tools (e.g., a pen). Precisely how that human is sensed by a machine drives the overall multimodal human–computer experience. However, before building high-performance multimodal systems, it is crucial that the architecture be based on an understanding of how humans communicate multimodally in different contexts.

Human Multimodal Interaction and Performance

There are large individual differences in ability and preference to use different modalities of communication, and one major advantage of a multimodal system is that it permits people to exercise selection and control over how they interact with a computer. In this respect, multimodal interfaces have the potentia to accommodate a broader range of users than traditional graphical user interfaces and unimodal interfaces – including users of different ages, skill levels, native language status, cognitive styles, sensory impairments, and other temporary or permanent handicaps or illnesses. Multimodal interfaces that incorporate modes such as speech, pen, touch, and gaze are also the preferred interface for supporting mobile tasks, since these input modes are compact and naturally portable. When combined, people can shift these input modes from moment to moment as environmental conditions change, which permits the alternation needed to cover a wider range of changing circumstances encountered during actual field use. The natural alternation between modes that is permitted by a multimodal interface also can be effective

in preventing overexertion and physical damage to any single modality, especially during protracted periods of computer use.

Compared with speech-only interaction, empirical work with users during visual–spatial tasks has demonstrated that multimodal pen–voice interaction can result in 10% faster task completion time, 36% fewer task-critical content errors, 50% fewer spontaneous disfluencies, and also shorter and more simplified linguistic constructions with fewer locative descriptions (Oviatt, 1997; Oviatt and Kuhn, 1998). This constellation of multimodal performance advantages corresponds to a 90–100% user preference to interact multimodally (Oviatt, 1997; Oviatt *et al.*, 1994). In large part, people's performance difficulties during visual–spatial tasks are due to their error-proneness and reluctance to articulate spatially oriented information. During multimodal interaction, people instead prefer to use pen input to point or create graphics, since it generally is a more effective and precise way to convey locations, lines, areas, and other inherently spatial information.

Recent work has revealed that a flexible multimodal interface can support users in managing their cognitive load. One study indicated that users spontaneously respond to dynamic changes in their own cognitive load by shifting to multimodal communication as load increases with task difficulty and communicative complexity (Oviatt *et al.*, 2004). Specifically, users' ratio of multimodal (versus unimodal) interaction increased substantially from 18.6% when referring to an already established dialogue context to 77.1% when they had to establish a new context. Likewise, multimodal interaction increased as tasks became more difficult, from 59.2% during low-difficulty tasks to 75.0% on very-high-difficulty tasks. These changes are believed to reflect users' efforts to self-manage limitations on working memory as complexity increases, which is accomplished by distributing communicative information across multiple modalities.

A particularly advantageous feature of multimodal interface design is its ability to support superior error handling, compared with unimodal recognition-based interfaces, in terms of both error avoidance and graceful recovery from errors (Oviatt *et al.*, 1999; Rudnicky and Hauptman, 1992; Suhm, 1998). Many of the reasons that multimodal systems facilitate error recovery are user centered. First, in a multimodal interface, users will select the input mode that they judge to be less error-prone for particular lexical content, which leads to error avoidance. Second, users' language is simplified when interacting multimodally, which reduces the complexity of natural language processing and thereby reduces recognition errors (Oviatt and Kuhn, 1998). Third, users have a strong tendency to switch modes after system errors, which facilitates error recovery because the confusion matrices differ for any given lexical content for the different recognition technologies involved in processing (Oviatt *et al.*, 1999). A fourth reason that multimodal systems support more graceful error handling is that users report less subjective frustration with errors when interacting multimodally, even when errors are as frequent as in a unimodal interface.

Significant efficiency advantages can also be found if system interfaces are designed to take advantage of the power of multimodal interaction. For spatially oriented tasks performed on desktop machines, that efficiency gain over graphical user interfaces has been found to range from 10% (Leatherby and Pausch, 1992) to a 400% increase in speed (Cohen *et al.*, 2000). Because the same multimodal interfaces can operate on smaller devices, the efficiency advantage is expected to be considerably larger as the device shrinks in size.

Independent of users' behavior, there are other system-centered reasons that multimodal systems yield superior error handling. The main reason is that a well-designed multimodal architecture can support 'mutual disambiguation' of input signals (Oviatt, 1999). Mutual disambiguation involves recovery from unimodal recognition errors within a multimodal architecture, because semantic information from each input mode supplies partial disambiguation of the other mode. For example, if a user says *ditches* but the speech recognizer confirms the singular *ditch* as its best guess, then parallel recognition of several graphic marks can result in recovery of the correct plural interpretation. This recovery can occur in a multimodal architecture even though the speech recognizer initially ranks the plural interpretation *ditches* as a less preferred choice on its *n*-best list. In two studies involving over 4,600 multimodal commands, a multimodal architecture was found to support mutual disambiguation and error suppression ranging between 19 and 41% (Oviatt, 2002a,b). Improved robustness also was greater for 'challenging' user groups (accented vs. native speakers) and usage contexts (mobile vs. stationary use). These results indicate that a well-designed multimodal system can perform not only with greater average reliability, but also in a more stable manner across varied real-world users and usage environments. To reap such error-handling advantages fully, a multimodal system must be designed so the modes provide duplicate functionality so users can accomplish their goals using either mode alone.

In the design of multimodal architectures, it is important to note that data on the order of input modes and

average intermodal lags have been used to determine the likelihood that an utterance is multimodal versus unimodal and to establish temporal thresholds for fusion of input. Previous empirical work on multimodal pen–voice integration patterns has revealed two main types of user: those who habitually deliver speech and pen signals in an overlapped or simultaneous manner and others who synchronize signals sequentially with pen input preceding speech by up to 4 s (Oviatt *et al.*, 2003). A user's dominant integration pattern typically can be identified on his or her first multimodal command and it remains highly consistent (i.e., 88–97%) throughout his or her interaction with the computer. In addition, a user's dominant pattern is strikingly consistent and resistant to change, even when explicit instruction or strong selective reinforcement is delivered to encourage switching from a sequential to simultaneous pattern, or vice versa (Oviatt *et al.*, 2003). These findings indicate that future multimodal systems that can **detect and adapt to a user's dominant integration pattern** potentially could yield substantial improvements in system robustness and overall performance.

Within biology, experimental psychology, and cognitive neuroscience, a separate rapidly growing literature has clarified that multisensory perception and integration cannot be predicted by studying the senses in isolation. When individual modalities are merged during normal processing, nonlinear interaction effects and illusions dominate (Stein and Meredith, 1993). Examples include the McGurk effect (McGurk and MacDonald, 1976), spatial ventriloquism effects (Bertelson and deGelder, 2004), temporal ventriloquism effects (Welch *et al.*, 1986), and cross-modal matching on pitch, loudness, brightness, and other features (Marks, 1989). Large individual differences and within-subject stability likewise have been documented in the perception of multisensory synchrony between auditory and visual events (Mollon and Perkins, 1996). Contrary to the historical focus on studying perceptual senses individually, multisensory processing effects now are viewed as pervasive and fundamental to the understanding of perception. These findings within cognitive science offer dynamic models of multimodal timing and fertile grounds for building the theoretical foundation needed to design future adaptive multimodal interfaces with greater flexibility, generality, and power. They also have the potential to define what it means to build a 'well-integrated' multimodal interface, including the circumstances under which so-called 'superadditivity' effects (i.e., mutual disambiguation) can be expected rather than interference between modalities (Spence and Driver, 1999).

Multimodal Collaboration

Computer support of human face-to-face communication is a very rich and relatively uncharted area of multimodal processing, although one that is now attracting researchers' attention. Numerous research groups (AMI, supported by the European Union, CHIL, supported by the European Commission's Sixth Framework Programme, and CALO, supported by the U.S. Defense Advanced Research Projects Agency) are now engaged in systematic data collection and analysis of multiparty meetings, incorporating information about people's speech, gesture, body posture, facial expression, and emotion, as well as information about the artifacts they use, their writing, sketch, and computer entry. These data are intended to provide a basis for understanding what people in fact do when they work together.

Although many studies have videotaped and attempted to analyze human–human dialogue, only recently have researchers attempted to build systems that can analyze such dialogues, providing the potential for computer support. First, there needs to be a base of understanding of how people engage in collaborative discourse. Of course, many disciplines have analyzed interpersonal dialogue, including ethnographers, educators, linguists, philosophers, and researchers in artificial intelligence, but often only at the linguistic level. Others have examined gesture in great detail (McNeill, 1992; Quek, 2003) but have not systematically and quantitatively studied the complete multimodal performance. When groups collaboratively use shared artifacts, the interaction becomes highly multimodal. In a recent study (Cohen *et al.*, 2003), it was found that for four military personnel collaborating over a horizontal paper map, 68% of utterances in a 20 min sample were multimodal, with a mean of 1.7 gestures per utterance (a maximum of 7 gestures, using both hands). Also, people often gestured within another person's utterance, and even collaborated on gesturing (e.g., by completing the other's gesture), much as they finish each other's sentences. Overall, collaborative interaction in various forms – lectures, meetings of various kinds, remote interaction – will be heavily multimodal, and significant research effort will be required to develop computer systems that can provide support.

Multimodal Architectures

Unlike graphical user interfaces, for which the user's inputs are certain, multimodal interfaces must first and foremost handle uncertainty – recognizers will always have some probability of error in processing

Figure 1 The many stages of multimodal integration.

human signals. Suited as they are to nontraditional computing environments, multimodal interfaces will also be confronted with substantial noise, perhaps in many channels simultaneously. Moreover, it is well known that there exists substantial variability in people's natural communication styles. Such interfaces need to handle variability at all levels, especially variability in human multimodal integration patterns, e.g., people's issuing of simultaneous and sequential input (Potamianos *et al.*, 2004; Oviatt *et al.*, 2003; McNeill, 1992; Kendon, 1980). An example of simultaneous input would be the use of the audio signal along with visual information about lip movement during speech recognition (see Potamianos *et al.*, 2004b, for an excellent review). An example of the latter would be speech and gesture integration, for which it is known that gesture often precedes the speech with which it should be combined (Oviatt *et al.*, 2003; McNeill, 1992; Kendon, 1980). The architecture also needs to be able to accommodate unimodal inputs, e.g., speech alone, iconic hand gestures, pen-based drawings. Some modalities provide meaningful information, whereas others, such as eye movements, may be useful as statistical predictors of human behavior in another mode. Systems thus need to function with whatever modality combinations the user chooses.

Figure 1 depicts a generic multimodal processing architecture, with a concentration, for expository purposes, on the language-processing pipeline. The architectural concepts discussed below also apply to other recognition/understanding processes, such as gesture understanding.

Assume that the speech recognition pipeline converts acoustic signals to phonemes and then to words, utterance, and meaning. In parallel, the user's lip, hand, arm, eye, pen, and torso motions are sensed by a variety of means (computer vision, magnetic or acoustic sensors, touch-sensitive surfaces, digital paper, etc.), characterized in various feature spaces, and then classified and understood. Multimodal processing needs to fuse these classifications with the language stream in order to arrive at the best joint interpretation of the multiple inputs. From Figure 1 we see that it is not clear where the information derived from processing the other individual modalities should affect the speech recognition and understanding process – that information could be merged during the signal processing, after the identification of constituent items, such as phonemes or syllables, during the search for words, the parsing of utterances, or the determination of meanings. Likewise, speech processing could be used to help understand input from the other modes, especially gesture, writing, or sketch. In the next section, we discuss three approaches to the architecture of multimodal fusion.

For ease of exposition, we use speech understanding as the base modality into which others will be integrated. Three approaches to modality fusion, early, intermediate, and late, can be applied: (1) during speech recognition, (2) during the language processing, and (3) after a linguistic meaning has been derived. We illustrate how these three approaches apply at different stages, both within a recognizer and further down the pipeline. Thus, depending on the granularity of the recognition or understanding process, a mid- to late-fusion algorithm at the stage of speech recognition is still an early-stage fusion process when one considers the larger process of spoken

Figure 2 Early-stage multimodal fusion architectures.

language understanding. Moreover, the information sources can be combined, and each might be best utilized at a different stage of the pipeline.

Early or feature-level fusion involves joint recognition based on a merger or concatenation of synchronized feature streams (see Figure 2). An example would be audiovisual speech recognition for which auditory and visual features are incorporated into one larger feature vector. Because these signal streams are produced from the same physical source – the human facial and vocal tract apparatus – audio information and visual information about speech are relatively well correlated in time. Audio features have been combined with visual features (so-called visemes (Potamianos *et al.*, 2004b; Bregler and Konig, 1994; Stork and Hennecke, 1995) into a combined feature vector that is then dimensionally reduced and subject to a relatively standard hidden Markov Model (HMM) speech recognition decoder. A single-stream HMM receives the concatenated feature vector (as depicted in Figure 2, left panel) or multiple features streams (Figure 2, right panel) are fed into a state-synchronous, multistream hidden Markov Model (Gravier *et al.*, 2002). More complex HMMs can be employed that factor the state space as a 'product' of states (Potamianos *et al.*, 2004) or coupling of the states (Brand *et al.*, 1997) (as in Figure 2, right panel). A second example of early fusion would be multisensory microphone technologies that combine acoustic signals transmitted through the air, with signals transmitted through bone or skin (e.g., throat) (Graciarena *et al.*, 2003; Zhang *et al.*, 2004; Zheng *et al.*, 2003).

Intermediate-level fusion (Figure 3) occurs when some amount of recognition has been carried out on at least one feature stream, which results in partial classification (such as into phonemes). However, a decision has not yet been reached about the final output classification (e.g., as words). The intermediate fusion process merges the additional modality information after the partial classification has been

Figure 3 Intermediate-stage fusion.

carried out. One application of this approach during speech recognition is again audiovisual processing of speech. Because audio information and visual information are often asynchronous by as much as 120 ms, which is approximately the length of a phoneme, some researchers have investigated the intermediate-stage merger of information at phoneme boundaries, leading to phone-synchronous multistream product hidden Markov models (Potamianos *et al.*, 2004a).

At the linguistic level, Bangalore and Johnston (2000) have experimented with intermediate-stage fusion by providing gestural information during speech recognition. In this approach, finite-state recognition subgrammars that incorporate information from a small class of pen-based gestures are downloaded dynamically into the speech recognizer to be used as language models. The gesturally based subgrammars then alter the speech recognition search for words (e.g., deictics such as 'this') that typically co-occur with gestures. This approach relies on empirical results that indicate that people usually draw or gesture before or while speaking (Oviatt and van Gent, 1996). Other researchers have restricted the system's recognition vocabulary by identifying the objects that the user can see (Roy and Mukherjee, in press; Yu and Ballard, 2003). However, information in such architectures tends to flow only one way, restricting speech

Figure 4 Late or decision fusion.

with gestural or object identification information, but not vice versa.

Finally, late or decision fusion (Figure 4) combines the results from classifiers, using statistical and/or semantic information. For audiovisual speech recognition, decision fusion algorithms combine the word classifications from audio and visual information, often with a linear combination of log-likelihoods of the classifications over the top-*n*-scoring class recognition hypotheses (or a lattice) in each modality (Potamianos *et al.*, 2004b). The weights applied in the combination can be trained to model variations in the confidence reported provided by the various recognizers themselves, or situation-specific experience about the success of a given recognizer. Overall, for audiovisual speech recognition, decision fusion methods have been found to outperform feature fusion methods (Potamianos *et al.*, 2004b; Potamianos and Neti, 2003), e.g., by a 12–17% relative reduction in word error rate (Potamianos and Neti, 2003). This approach also has a practical advantage of simplicity of implementation, allowing for independently developed 'black box' classifiers to be incorporated.

Further down the pipeline of Figure 1, late or decision fusion combines the results from individual speech and gesture understanding components, which may also be sensitive to contextually relevant information from the physical or discourse contexts (see Figure 4). Whereas late fusion at the word recognition stage involves recognizers that produce alternative classifications (e.g., word hypotheses), late fusion at the level of meaning representation derived from speech and gesture (for example) will fuse the classifications into a more comprehensive whole. Semantic combination methods have frequently been based on the unification of the meanings derived from each input (Johnston *et al.*, 1997; Vo and Wood, 1996; Yu and Ballard, 2003), whereas statistical classifier combination methods have involved a hierarchical classifier combination procedure (Oliver *et al.*, 2002; Wu *et al.*, in press). Hybrid methods that combine statistical and symbolic approaches have also been applied to derive the best-scoring joint ultimodal interpretations (Kaiser and Cohen, 2002).

In order to accomplish late-stage fusion at the level of meaning, the multimodal integration subsystem **unifies** the meaning representations derived from each mode (Johnston *et al.*, 1998), often with a statistical process to rank the fused hypotheses. Unification is a recursive matching process derived from automated theorem-proving and logic programming. Here, it is used to combine information from different modalities when represented in an attribute/value structure with shared variables. Unification combines redundant and complementary information from the two information sources, but rules out inconsistent information. By examining (a subset of) the cross product of the hypothesis lists from each modality, such an architecture is capable of 'mutual disambiguation' (MD) of the joint inputs (Oviatt, 1999). This fusion process searches the lists of hypotheses from each mode for the best-scoring unified multimodal hypothesis. MD occurs because the best joint hypothesis may in fact not use the top-rated modality hypothesis from any mode. When it does not, the method has disambiguated the poorer scoring modalities. For example, consider a case from a multimodal virtual reality system (Kaiser *et al.*, 2003) in which the user says *Rotate the monitor clockwise* while making a twisting movement with her hand. Figure 5 shows an instance of double mutual disambiguation in which the top-scoring multimodal hypothesis has combined the best speech hypothesis with the second-best gestural and third-best object identification hypotheses. Diagrammatically, when the line is not straight, MD has occurred.

Mutual disambiguation benefits a system most in challenging environments, where, at any given time, a channel of input can be corrupted by noise, physical movement, or other factors. Other modalities that are unaffected by that situational variable (e.g., gesture is likely to be unaffected by noise) can often provide sufficient disambiguating information.

The purpose of these architectures is to support robust system processing of people's multimodal performance in challenging environments. In the next section, we discuss how this robustness is achieved.

Robustness

There are many reasons that multimodal systems are more robust than unimodal ones. Empirical studies of multimodal human–computer interaction have found that, in comparison to speech-only interactions,

Figure 5 Example of double mutual disambiguation.

people change their language when allowed to communicate multimodally (Oviatt and Kuhn, 1998). Specifically, in a map-based task, it was found that multimodal utterances are shorter and less disfluent, with locative information being expressed gesturally rather than in complex (and disfluent) phrases. Thus, systems that allow users to distribute their content across modalities will face simpler recognition and understanding problems and thus are likely to be more robust.

A second major benefit for multimodal interaction is the opportunity to use other sources of information to compensate for recognition errors, especially in challenging environments. These benefits have been found with each stage of modality fusion.

At the early stage of spoken language understanding, the use of multisensory microphones that fuse bone-conduction signals with standard acoustic signals has been found to lower the ASR relative error rate by 50% (Zhang *et al.*, 2004; Zheng *et al.,* 2003). Research on audiovisual speech recognition has shown that the use of visual information in a studio environment lowers the relative error rate for large-vocabulary ASR by 8% in noisy environments (babble noise), which is the equivalent of lowering the noise level by 7dB (Potamianos *et al.*, 2004). Variation in lighting and pose can be overcome through the use of a multimodal microphone that incorporates both an infrared camera aimed at the lips and an audio microphone (Huang *et al.*, 2003). Using a feature fusion architecture, with multispeaker noise, the audiovisual headset accounted for a 53.7% relative reduction in word error rate.

In using a midstage fusion process of language understanding, Bangalore and Johnston (2000) found a relative reduction in the speech recognition errors of 23% through the incorporation of gesture. Roy and Pentland (2002) found a 31% RER in speech recognition by priming the speech recognition language model using the objects that the user could see.

Systems that do late fusion and examine the lists of hypotheses that arise from the various recognizers or interpreters support mutual disambiguation. Oviatt (1999) reported that MD led to a 41% relative error rate reduction (RER) for nonnative speakers of English, rendering their performance with the multimodal system on a par with that of native speakers. One in eight utterances succeeded because of MD. MD also helps in mobile contexts, which may have unpredictable noise, movement, and exertion. When using a high-quality noise-canceling microphone vs. a microphone onboard the computer, Oviatt *et al.* (2004) reported a 19% relative error rate reduction of speech recognition due to the fusion of pen-based gesture and a 30% RER for speech recognition because of multimodal interaction, when subjects were walking vs. stationary. Kumar *et al.* (2004) reported a 35% RER for speech recognition when subjects were highly exerted, with a stable overall multimodal system performance compared to that of a stationary user. For highly exerted users, 16% of multimodal inputs succeeded in virtue of MD. Finally, when a multimodal virtual/augmented reality system had access to four types of information in arriving at a joint interpretation – sets of hypotheses about the user's speech, his or her 3D arm gestures, a set of objects in the virtual world that were potentially being referred to, and a set of objects that were in view (derived from head position) – MD led to a 67% RER for multimodal interpretations over the performance of the system that fused only the top-scoring hypothesis from each information source (Kaiser *et al.*, 2003). Thus, increased levels of robustness may be found by combining more sources of information.

Multimodal Language Processing

Many researchers have built systems that incorporate both natural language and gesture, especially mouse, touch, pen, and 3D gesture. Such systems often embodied the assumption that the processing of spoken language is central, with the processing of other modes based on its control strategy. Indeed, many systems were built with the assumption that human use of gestural modes would be flagged in any utterance by a deictic determiner (e.g., *this*, *these*). Thus, when a parser detected a deictic determiner, it would look in its buffer of deictically indicated objects (again, assuming that the function of the secondary modes was deixis) for the referent(s). Unfortunately, the assumptions that guided the early systems were falsified by examination of user data. Frequently, users of multimodal pen–voice systems would speak and draw, but not issue a deictic expression (e.g., *Show me <draws circle on an object>*) (Oviatt, 1997). Users of multimodal virtual reality systems often issued commands with gestures indicating the manner of action (e.g., *Rotate the monitor clockwise <rotate gesture>*) (Kaiser *et al*., 2003; Corradini and Cohen, 2002). Without a deictic phrase, these language-centric systems would thus not detect the gesture. The upshot of these results is that multimodal systems need to be built to accommodate modalities equally – any combination of modes should be allowed, but subject to empirically discovered constraints on human behavior.

Another empirical finding about multimodal interaction with implications for the language processing is the observation that people cluster into two groups in terms of how they integrate speech and gesture – they either provide gesture and speech sequentially (usually with gesture preceding speech) with a gap between gesture and speech of no more than 4 s (for a pen–voice interface) or they provide their output simultaneously. Not only do they not tend to speak and then gesture, they have a consistent integration style, which they resist changing (Oviatt *et al*., 2004). This latter finding has obvious implications for adaptive processing. In general, the sequential nature of some users' multimodal performance indicates that a spoken language analysis system cannot rely on precise time synchronization to locate the relevant information in other modalities with which to integrate.

In coping with actual human data, multimodal language interpretation has involved the development of multimodal grammar rules that are parsed by a unification-based multidimensional chart parser (Johnston, 1998; Denecke and Yang, 2000). The rules specify how meaning representation fragments derived from any collection of modalities combine into larger structures. Examples could be noun phrases with deictically specified gestures, or visual language rules that specify how sketched shapes combine to form larger structures (e.g., a flow chart). Unlike the aforementioned speech-centric approaches to multimodal integration in the literature, the multimodal grammar rules are independent of modality and thus do not require that speech dominate any analysis. Because users may issue both unimodal and multimodal actions (Oviatt, 1997, 1999), multimodal parsing also involves empirically derived temporal constraints (Oviatt, 1997; Oviatt *et al*., 1997) that can 'bracket' the various inputs, providing guidance on which should be interpreted together and which alone. For example, because gesture tends to precede speech for a habitually sequential user, a sequence of Gesture_1, Speech, Gesture_2 should most likely have (Gesture_1, Speech) interpreted together followed by Gesture_2 alone. Similarly, spatial constraints are also common in these rules, especially for sketch understanding.

Johnston (2002) discussed various alternative architectures that combine spoken language with multimodal parsing. In earlier systems (e.g., Johnston *et al*., 1997; Johnston, 1998), multimodal parsing and spoken language parsing were combined in a multidimensional chart parser. However, it is argued that combinatorics of parsing can be better managed by interleaving spoken language and multimodal parsing, such that deictic noun phrases are parsed and integrated separately by the multimodal subsystem, with the results returned back to the spoken language parser. Other phrases, such as manner adjuncts (e.g., *this way <gesture>*), can also be handled in the same fashion. However, the architecture still needs to be sensitive to the existence of gestures that may not be marked linguistically, but contribute to the overall meaning.

Future Research and Development

The science and technology of multimodal interaction are progressing rapidly. Research is examining not only how spoken language, gesture, eye gaze, body movement, and other modalities can be integrated, but also is investigating how more than two modalities can be combined, in order to achieve greater degress of robustness in challenging environments. Expanding our purview, multimodal interaction will begin to become integrated with dialogue and task context in order to further reduce uncertainties inherent in the underlying recognition-based technologies. Collaborative multiparty multimodal interaction is also affording fascinating challenges to current multimodal science and technology, often undermining long-held assumptions and simplifications. Moreover,

though we could not explore the topic of multimodal output processing in this paper, the planning of a multimodal presentation with coordinated graphics and language that achieves the system's goals is receiving substantial interest among researchers. Future research will strive to build systems that can take advantage of scientific knowledge of humans' multisensory perceptual capabilities to build systems that can design presentations on the fly that are maximally effective for the task at hand.

The emerging base of science and technology is now spawning a nascent industry. Multimodal systems are now being sold commercially, including multimodal map systems (Advanced Interfaces' GeoMip, and Natural Interaction Systems's NISMap systems), computer-aided design (Think3), personal information management (Microsoft's MiPAD), and cellular telephony (IBM, Kirusa, Motorola, Nokia,) products. In the last case, multimodal interfaces are likely to be the preferred user interface paradigm for interacting with small devices. Most current products offer multiple modalities as alternatives (e.g., voice or touch), but future products will undoubtedly attempt modality fusion with the goal of increased robustness and expressivity. Many other corporations are experimenting with multimodal product solutions.

Multimodality and the Language of Politics

R Scollon, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

The term 'multimodality' is now used by many scholars to capture an emerging perspective on language and communication. Although such scholars differ considerably in what is considered to be a separate mode and in the ways in which these modes may interact, all take it that any use of language is inescapably multimodal. That is, spoken or written language inherently cooccurs in grammatical interactions among other semiotic modes such as gesture, image, color, texture, shape, or spatial layout and configuration.

In multimodal analysis, written text is analyzed together with text shape, typography, print color and paper, and graphic and photographic images (Kress and van Leeuwen, 1998, 2001). Spoken utterances are most commonly analyzed together with the speaker's gestures, posture, and physical placement and movement in the moment of speaking (McNeill, 1992). There is a growing interest in the analysis of relations among speech (gesture, etc.), and writing (screen scrolling text or captioning), in television and computer-displayed communications (Chouliaraki, 2004), but relatively less research that focuses on the semiotics of the spaces and places in which communications are produced or uttered (Scollon and Scollon, 2003; Crang, 1998; Crang and Thrift, 2000; Norris, 2004).

Research on the language of politics within a multimodal perspective has begun to range considerably beyond traditional printed newspaper accounts or tape-recorded and transcribed radio and television accounts of the language of political figures. Such research makes central use of ethnographic methodologies, and now includes the comparison of printed and spoken statements, the study of the production of political texts through the study of the discursive histories of political statements and policies, and the use of graphics, photographs, videos, and other images in television and internet presentations of news stories. Further, scholars take it to be of central importance in their analyses to see, record, and analyze not only the text, nor only the moment and contexts in which political statements are made, but also the vastly distributed moments in which political language is taken up by readers or viewers in the conduct of their daily lives (Wodak, 2001; Reisigl and Wodak, 2001; Chouliaraki, 2004; Dunne, 2003; Blommaert, 2005).

The linguistic study of language and politics within a multimodal perspective has consequently broadened to encompass a complex interdisciplinary field of study (Lemke, 2002). Linguists are becoming interested in design, typography, or cultural geography, as necessary disciplines in the study of the social, physical, and spatial use of language. Designers or typographers are becoming interested in the formal means used by discourse analysts to study such semiotic relationships as focus, theme, transitivity,

The term 'multimodality' is now used by many scholars to capture an emerging perspective on language and communication. Although such scholars differ considerably in what is considered to be a separate mode and in the ways in which these modes may interact, all take it that any use of language is inescapably multimodal. That is, spoken or written language inherently cooccurs in grammatical interactions among other semiotic modes such as gesture, image, color, texture, shape, or spatial layout and configuration.

In multimodal analysis, written text is analyzed together with text shape, typography, print color and paper, and graphic and photographic images (Kress and van Leeuwen, 1998, 2001). Spoken utterances are most commonly analyzed together with the speaker's gestures, posture, and physical placement and movement in the moment of speaking (McNeill, 1992). There is a growing interest in the analysis of relations among speech (gesture, etc.), and writing (screen scrolling text or captioning), in television and computer-displayed communications (Chouliaraki, 2004), but relatively less research that focuses on the semiotics of the spaces and places in which communications are produced or uttered (Scollon and Scollon, 2003; Crang, 1998; Crang and Thrift, 2000; Norris, 2004).

Research on the language of politics within a multimodal perspective has begun to range considerably beyond traditional printed newspaper accounts or tape-recorded and transcribed radio and television accounts of the language of political figures. Such research makes central use of ethnographic methodologies, and now includes the comparison of printed and spoken statements, the study of the production of political texts through the study of the discursive histories of political statements and policies, and the use of graphics, photographs, videos, and other images in television and internet presentations of news stories. Further, scholars take it to be of central importance in their analyses to see, record, and analyze not only the text, nor only the moment and contexts in which political statements are made, but also the vastly distributed moments in which political language is taken up by readers or viewers in the conduct of their daily lives (Wodak, 2001; Reisigl and Wodak, 2001; Chouliaraki, 2004; Dunne, 2003; Blommaert, 2005).

The linguistic study of language and politics within a multimodal perspective has consequently broadened to encompass a complex interdisciplinary field of study (Lemke, 2002). Linguists are becoming interested in design, typography, or cultural geography, as necessary disciplines in the study of the social, physical, and spatial use of language. Designers or typographers are becoming interested in the formal means used by discourse analysts to study such semiotic relationships as focus, theme, transitivity,

grammatical mode, or tense and aspect. There is also an increased interest among cultural geographers in discourse analysis and social theory. Hence, these multimodal theorists now see political life as a complex process by which meaning is produced across many modes; and therefore, the analysis of the language of politics is beginning to incorporate methods, and theoretical tools from disciplines that only a few years ago were rarely referenced by linguists and discourse analysts.

Multivalued Logics

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Logic is the formal discipline establishing *calculi of entailments*. A sentence, or set of sentences, A *entails* a sentence B just in case in all cases where A is true, B must also be true on account of the meanings of A and B (on analytical grounds). Since meanings are varied and manifold, it is, in general, not possible formally to *compute* entailments: most entailments are recognized intuitively. Aristotle discovered, however, that in some cases entailments can be computed with the help of specific words, the logical constants, whose semantic properties are precise enough to allow for formal computation. The logical constants usually recognized are *all* and *some* for quantification theory (predicate logic), and *not*, *and*, *or,* and *if* for both predicate and propositional logic. When an entailment is computable by virtue of one or more of the logical constants, it is a *logical* entailment.

Standard modern logic is firmly based on the Aristotelian *Principle of Bivalence*, also known as the *Principle of the Excluded Third* (PET), which says that (a) all propositions always have a truth value, and (b) there are exactly two truth values, 'true' (T) and 'false' (F), without any transitional values, and without any values outside T and F. Some logicians have queried the validity of PET with regard to natural language.

Strawson's attempt at infringing PET (Strawson, 1950, 1952) is most widely known among linguists and semanticists. His 'gapped bivalent logic' keeps the values T and F but introduces the possibility of a 'truth-value gap' for sentences without any truth value. Strawson thus violated subprinciple (a) of PET, in that he allowed for propositions (sentences) without a truth value. He never provided a formal account of this logic, but one surmises that it is identical to standard propositional calculus, except that a logically complex sentence lacks a truth value when at least one of the component propositions (sentences) does so: lack of truth value is 'infectious.' Lack of truth value, in Strawson's analysis, is the fate incurred by sentences that suffer from presupposition failure. The main empirical problem with this analysis (besides problems of a metalogical nature) is that such sentences are generally judged to be false, while their negations are judged to be true (*see* **Presupposition**).

Other logicians have developed nonbivalent logics that infringe subprinciple (b) of PET. The linguistic justification for such logics is the consideration that if the predicates 'true' and 'false' in natural language

grammatical mode, or tense and aspect. There is also an increased interest among cultural geographers in discourse analysis and social theory. Hence, these multimodal theorists now see political life as a complex process by which meaning is produced across many modes; and therefore, the analysis of the language of politics is beginning to incorporate methods, and theoretical tools from disciplines that only a few years ago were rarely referenced by linguists and discourse analysts.

Multivalued Logics

P A M Seuren, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Logic is the formal discipline establishing *calculi of entailments*. A sentence, or set of sentences, A *entails* a sentence B just in case in all cases where A is true, B must also be true on account of the meanings of A and B (on analytical grounds). Since meanings are varied and manifold, it is, in general, not possible formally to *compute* entailments: most entailments are recognized intuitively. Aristotle discovered, however, that in some cases entailments can be computed with the help of specific words, the logical constants, whose semantic properties are precise enough to allow for formal computation. The logical constants usually recognized are *all* and *some* for quantification theory (predicate logic), and *not*, *and*, *or,* and *if* for both predicate and propositional logic. When an entailment is computable by virtue of one or more of the logical constants, it is a *logical* entailment.

Standard modern logic is firmly based on the Aristotelian *Principle of Bivalence*, also known as the *Principle of the Excluded Third* (PET), which says that (a) all propositions always have a truth value, and (b) there are exactly two truth values, 'true' (T) and 'false' (F), without any transitional values, and without any values outside T and F. Some logicians have queried the validity of PET with regard to natural language.

Strawson's attempt at infringing PET (Strawson, 1950, 1952) is most widely known among linguists and semanticists. His 'gapped bivalent logic' keeps the values T and F but introduces the possibility of a 'truth-value gap' for sentences without any truth value. Strawson thus violated subprinciple (a) of PET, in that he allowed for propositions (sentences) without a truth value. He never provided a formal account of this logic, but one surmises that it is identical to standard propositional calculus, except that a logically complex sentence lacks a truth value when at least one of the component propositions (sentences) does so: lack of truth value is 'infectious.' Lack of truth value, in Strawson's analysis, is the fate incurred by sentences that suffer from presupposition failure. The main empirical problem with this analysis (besides problems of a metalogical nature) is that such sentences are generally judged to be false, while their negations are judged to be true (*see* **Presupposition**).

Other logicians have developed nonbivalent logics that infringe subprinciple (b) of PET. The linguistic justification for such logics is the consideration that if the predicates 'true' and 'false' in natural language

allow for degrees, or if there are different kinds of truth and/or falsity, then it should be possible to devise logical calculi reflecting the different degrees or kinds of truth and falsity. It has turned out that this is not only possible but also highly enlightening.

Apart from PPC_3, to be discussed in a moment, the main developments in formal multivalued logics occurred between the 1920s and the 1950s, as an outflow of the formalization of logic that had just occurred, with C. S. Peirce as an early precursor (Rescher, 1969: ch. 1). The multivalued logics developed in that period are all restricted to propositional calculus – that is, to truth tables for the logical constants (the so-called connectives) *not*, *and*, *or*, and *if*. Extensions to predicate logic, where the logic of the quantifiers *all* and *some* is defined, were not attempted. Moreover, all multivalued logics (apart from Strawson's gapped bivalent logic) developed during the period mentioned work with a value 'intermediate' or 'undefined.' They were devised to provide logical accounts for future contingency (J. Łukasiewicz), modalities (C. S. Peirce), intuitionism (A. Heyting), logical paradoxes (D. A. Bochvar), or undecidable mathematical statements (S. C. Kleene). There is a great deal of overlap among the logical machineries proposed by these authors.

The more interesting multivalued logics are extensions of standard bivalent logic, in the sense that there is, for each type of extension L^m, an algorithm that generates the precise form of L^m for any desired number of truth values in such a way that the theorems of standard logic, with the operators $\neg$, $\wedge$, and $\vee$, are preserved. That is, they are closed under $\{\neg, \wedge, \vee\}$. One may repeat what Peirce wrote in a letter to William James in 1909 (Rescher, 1969: 5): "The recognition [of multivalued logics] does not involve any denial of existing logic, but it involves a great addition to it."

The best known, and most fruitful, system is Kleene's trivalent logic (Kleene, 1938, 1952), with the values 'true' (T), 'false' (F), and 'intermediate' (I). This logic thus violates subprinciple (b) of PET as defined earlier. Kleene's truth tables are as shown in Figure 1, with '$\sim$' for Kleene's trivalent negation, '$\wedge$' for conjunction, and '$\vee$' for disjunction (the implication is definable as '$\sim A \vee B$.' One sees that the negation '$\sim$' turns T into F and vice versa, and leaves I unaffected; conjunction selects the lowest of the values of the component sentences A and B ($T > I > F$); disjunction selects the highest of the values of A and B. This accounts for the fanlike arrangement of the values T, I, and F in the tables for conjunction and disjunction. Kleene's calculus has no operator turning I into T. Such an operator can be added to the system by letting '?A' produce T for I, and F for both T and F. The standard bivalent negation operator '$\neg$' also finds a place in this system, in that it turns T into F and all other values into T (it simply says that A is not true). One notes that $\neg$ is the disjunction (union) of $\sim$ and ?: $\sim A \vee ?A \equiv \neg A$.

The algorithm for generating Kleene logics with an unlimited number of values is simple. For an *n*-valued Kleene logic ($n \geq 2$), let the highest value be T, and the lowest F. All intermediate values I^i ($i \leq n-2$) are optional and are ranked between T and F. Then $\sim$ turns T into F and vice versa, and leaves all I^i unaffected; $\wedge$ selects the lowest of the values of A and B; $\vee$ selects the highest of the values of A and B. $?^i$ turns the intermediate value I^i into T and all other values into F. An extension of the value I to an infinite number of intermediate values generates the multivalued 'fuzzy' logic of Zadeh (1975). Standard bivalent logic is merely the minimal variant of this Kleene family of logics, with $n = 2$ and without any intermediate values.

Although Kleene developed his logic with a mathematical purpose in mind (to account for undecidable mathematical statements), it is of specific linguistic interest in that it appears to account for cases of vagueness, in the sense of neither clearly true nor clearly false, as when one can say of a dimly lit room either that it is dark or light.

A different trivalent propositional calculus, likewise extendable to any number of truth values, was developed in Seuren (1985) for the specific purpose of capturing the logical properties of presupposition. This calculus, *trivalent presuppositional propositional calculus*, or PPC_3, distinguishes between two kinds of falsity. For logically atomic sentences, radical falsity (F2) ensues when there is presupposition failure; minimal falsity (F1) ensues when all presuppositions

A	~A	?A	¬A
T	F	F	F
I	I	T	T
F	T	F	T

∧		B: T	B: I	B: F
A	T	T	I	F
	I	I	I	F
	F	F	F	F

∨		B: T	B: I	B: F
A	T	T	T	T
	I	T	I	I
	F	T	I	F

Figure 1 Truth tables of Kleene's trivalent propositional calculus.

A	~A	≃A	¬A
T	F1	F1	F1
F1	T	F1	T
F2	F2	T	T

∧ (A \ B)	T	F1	F2
T	T	F1	F2
F1	F1	F1	F2
F2	F2	F2	F2

∨ (A \ B)	T	F1	F2
T	T	T	T
F1	T	F1	F1
F2	T	F1	F2

Figure 2 Truth tables of PPC_3.

are true but an update condition of the main predicate is not satisfied (*see* **Presupposition; Lexical Conditions**). Thus, a sentence like *The present queen of England is bald* is valued F1, because no presupposition is violated, but the person in question happens not to be bald. By contrast, a sentence like *The present king of France is bald* is valued F2 because the existential presupposition that there is such a person is not fulfilled.

The first proposal to this effect was made in Dummett (1973: 421), also on grounds of presuppositional phenomena, though more from a philosophical than from an observational point of view: Dummett does not provide an actual trivalent logical system incorporating the two kinds of falsity. He also considered the possibility of two kinds of truth – a suggestion that should be taken seriously but is not elaborated here. The logical system that corresponds to Dummett's suggestion is PPC_3. Yet it must be emphasized that PPC_3 does not *define* presupposition in natural language. Presupposition is defined by its purely linguistic and semantic characteristics (*see* **Presupposition**). PPC_3 is merely meant as a description of the epiphenomenal logical properties of presupposition.

In PPC_3 there are two negations, a *minimal negation* '$\sim$' turning T into F1, F1 into T, and leaving F2 unchanged, and a *radical negation* '$\simeq$' turning both T and F1 into F1 and F2 into T. The standard bivalent negation $\neg$ can be added for good measure: it turns T into F1 and all other values into T. Moreover, the conjunction $\wedge$ selects the lowest ($T > F1 > F2$), and the disjunction $\vee$ selects the highest of the component values. This gives the tables of Figure 2, again with the typical fanlike arrangement for conjunction and disjunction observed in Figure 1.

The algorithm for extension to *n* truth values with one value T and *n*–1 values F^i ($i \geq n-1$) is again simple. Define a specific negation '$\sim^i$' for each kind of falsity. $\sim^i$ turns F^i into T, all higher values ($T > F^1, \ldots > F^{n-1}$) into F^1 and leaves all lower values unaffected. $\wedge$ selects the lowest, and $\vee$ selects the highest of the component values. Again, standard bivalent logic is merely the minimal variant of this family of logics, with the values T and F^1 and the one specific negation $\sim^1$, which then equals standard $\neg$. Again, $\neg$ is the disjunction (union) of $\sim^1$ to $\sim^{n-1}$: $\sim^1 A \vee \sim^2 A \vee \ldots \vee \sim^{n-1} A \equiv \neg A$.

The two families – the Kleene family and the PPC_n family – can be combined into one large family with any number of intermediate values between any two values of the PPC_n system. Which selection of this wealth of possible logical options suits the facts of natural language best is an empirical question. The theory of language benefits substantially from this widening of the range of available options. Before multivalent logics were discovered, there was only one option for the logic of the propositional operators, the standard bivalent system, and there was, therefore, no empirical question because there was no choice. The extension of logical space in various directions has given rise to the empirical question of what the correct logic of language amounts to.

Research into the empirical question just formulated is relatively recent. What has been found so far suggests that a system like PPC_3 with an infinite set of Kleenean intermediate values between T and F1 appears to stand a reasonable chance of providing a suitable frame for an adequate analysis and description of the logical properties of the propositional connectives, including negation, in human language.

Munda Languages

G D S Anderson, University of Oregon, Eugene, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

'Munda' is a group of languages belonging to the Austroasiatic language family spoken in eastern and central India, primarily in the states of Orissa, Jharkand, Bihar, and Madhya Pradesh and in adjacent areas of West Bengal, Maharashtra, and Andhra Pradesh. Some Munda speakers are found in expatriate or diaspora communities throughout India, Nepal, and western Bangladesh as well. In earlier literature, Munda is often referred to as Kol or Kolarian.

The Munda language family recognizes a major split between a North Munda and a South Munda subgroup. Within the North Munda subgroup, there is a binary opposition between Korku and a large group of Kherwarian languages, which is perhaps more properly described as a dialect continuum. Kherwarian includes both the largest of the Munda languages, Santali, with nearly 7 million speakers, as well as some of the smallest, such as Birhor, with under 1000. Other noteworthy North Munda languages include Mundari and Ho, each with approximately 1 million speakers, and smaller languages such as Agariya, Asuri, Bhumij (Mundari), Karmali Santali, Koraku, Korwa, Mahali, and Turi. Publications may be found in the larger of the Kherwarian languages (Mundari, Ho, Santali), including a range of Santali publications in a native orthography (the Ol' Cemet script). Short wave radio broadcasts are also available in Santali. The newly founded 'tribal' state of Jharkhand has a Munda-speaking majority and is lobbying to have some form of Kherwarian declared another state language of India.

The South Munda subgroup is older and more internally diversified than North Munda. At least the following languages belonging to this subgroup: Sora (Savara), Juray, Gorum (Parengi, Parenga), Gutob (Gadaba, Bodo), Remo (Bonda, Bondo), Gtaʔ (Gataʔ, Didey), Kharia, and Juang. In terms of further subgrouping, it is clear that Sora and Gorum form a branch of their own, as do the closely related Gutob and Remo. Gtaʔ, which is properly speaking two separate languages: the poorly known Hill Getaʔ and Plains/Riverside Getaʔ, has been traditionally linked at a slightly higher taxonomic level with Gutob-Remo (so-called Gutob-Remo-Gtaʔ), and Kharia and Juang have been linked together in a branch as well. These latter two classifications are tenuous and remain to be adequately demonstrated (Anderson, 2001). South Munda languages range in total number of speakers from 300 000 or more Sora speakers to between 150 000 and 200 000 Kharia speakers to Gutob with approximately 30 000–50 000 total speakers and Juang with around 15 000 speakers. The remaining South Munda languages have around 2000–4000 speakers each.

Typologically speaking, all Munda languages are moderately to extensively agglutinating, show SOV basic clause structure, and possess preglottalized or unreleased 'checked' consonants. This latter feature is quintessentially Munda, and readily distinguishes Munda languages from the surrounding languages of the subcontinent.

The shift to SOV word order from SVO to VSO may be attributed to influence from Indo–Aryan or Dravidian languages (Anderson, 2003), which varies from moderate to strong in individual Munda languages. Generally speaking, the southernmost South Munda languages show the greatest degree of structural influence from local tribal Dravidian and lexical influence from the local tribal Indo–Aryan (e.g., Desia/Kotia Oriya). In addition, Kharia has been heavily influenced by Kherwarian North Munda languages such as Mundari.

Kherwarian North Munda languages are characterized by a high degree of morphological complexity, standing out even within the morphologically rich languages of South Asia. Among the most noteworthy characteristic features of Kherwarian verb structure is

'Munda' is a group of languages belonging to the Austroasiatic language family spoken in eastern and central India, primarily in the states of Orissa, Jharkand, Bihar, and Madhya Pradesh and in adjacent areas of West Bengal, Maharashtra, and Andhra Pradesh. Some Munda speakers are found in expatriate or diaspora communities throughout India, Nepal, and western Bangladesh as well. In earlier literature, Munda is often referred to as Kol or Kolarian.

The Munda language family recognizes a major split between a North Munda and a South Munda subgroup. Within the North Munda subgroup, there is a binary opposition between Korku and a large group of Kherwarian languages, which is perhaps more properly described as a dialect continuum. Kherwarian includes both the largest of the Munda languages, Santali, with nearly 7 million speakers, as well as some of the smallest, such as Birhor, with under 1000. Other noteworthy North Munda languages include Mundari and Ho, each with approximately 1 million speakers, and smaller languages such as Agariya, Asuri, Bhumij (Mundari), Karmali Santali, Koraku, Korwa, Mahali, and Turi. Publications may be found in the larger of the Kherwarian languages (Mundari, Ho, Santali), including a range of Santali publications in a native orthography (the Ol' Cemet script). Short wave radio broadcasts are also available in Santali. The newly founded 'tribal' state of Jharkhand has a Munda-speaking majority and is lobbying to have some form of Kherwarian declared another state language of India.

The South Munda subgroup is older and more internally diversified than North Munda. At least the following languages belonging to this subgroup: Sora (Savara), Juray, Gorum (Parengi, Parenga), Gutob (Gadaba, Bodo), Remo (Bonda, Bondo), Gtaʔ (Gataʔ, Didey), Kharia, and Juang. In terms of further subgrouping, it is clear that Sora and Gorum form a branch of their own, as do the closely related Gutob and Remo. Gtaʔ, which is properly speaking two separate languages: the poorly known Hill Getaʔ and Plains/Riverside Getaʔ, has been traditionally linked at a slightly higher taxonomic level with Gutob-Remo (so-called Gutob-Remo-Gtaʔ), and Kharia and Juang have been linked together in a branch as well. These latter two classifications are tenuous and remain to be adequately demonstrated (Anderson, 2001). South Munda languages range in total number of speakers from 300 000 or more Sora speakers to between 150 000 and 200 000 Kharia speakers to Gutob with approximately 30 000–50 000 total speakers and Juang with around 15 000 speakers. The remaining South Munda languages have around 2000–4000 speakers each.

Typologically speaking, all Munda languages are moderately to extensively agglutinating, show SOV basic clause structure, and possess preglottalized or unreleased 'checked' consonants. This latter feature is quintessentially Munda, and readily distinguishes Munda languages from the surrounding languages of the subcontinent.

The shift to SOV word order from SVO to VSO may be attributed to influence from Indo–Aryan or Dravidian languages (Anderson, 2003), which varies from moderate to strong in individual Munda languages. Generally speaking, the southernmost South Munda languages show the greatest degree of structural influence from local tribal Dravidian and lexical influence from the local tribal Indo–Aryan (e.g., Desia/Kotia Oriya). In addition, Kharia has been heavily influenced by Kherwarian North Munda languages such as Mundari.

Kherwarian North Munda languages are characterized by a high degree of morphological complexity, standing out even within the morphologically rich languages of South Asia. Among the most noteworthy characteristic features of Kherwarian verb structure is

the extensive system of referent indexing that includes, subjects, objects (direct and indirect), benefactives, and possessors as well. An example of this type of marking may be seen in the following Santali form:

(1) Santali (North Munda)
sukri-ko gɔ'c-ke-d-e-tiñ-a
pig-PL die-ASP-TR-3-1POSS-FIN
'they killed my pig'
(Bodding, 1929: 209)

South Munda languages show a lesser degree of morphemic complexity than their sister languages to the north. Making this assertion is not to say that large complexes are not found among the South Munda languages, however. All South Munda languages reflect some degree of noun incorporation, either as an active morphosyntactic process (Sora, Gtaʔ) or preserved only in lexicalized formations (Kharia). In fact, Sora is among the very small number of the world's languages that allows for both instances of multiple noun incorporation (2), as well as the typologically unusual agent incorporation with transitive verbs (3).

(2) Sora (South Munda)
jo-me-bob-dem-te-n-ai
smear-oil-head-RFLXV-NPAST-INTR-CLOC/1
'I will anoint my head with oil'
(Ramamurti, 1931: 143)

(3) Sora (South Munda)

ñam-kit-t-am	*sa-bud-t-am*
seize-tiger-NPAST-2	mangle-bear-NPAST-2
'tiger will seize you'	'bear will mangle you'
(Ramamurti, 1931: 40)	(Ramamurti, 1931: 142)

South Munda languages also show agreement in the verb with a possessor of a logical argument, but unlike Santali, which utilizes a special set of possessive inflectional suffixes, South Munda languages like Gorum show the more typologically 'normal' pattern of 'Possessor Raising' (4), raising the possessor to term argument and encoding it in the verb in a manner identical to object marking.

(4) Gorum (South Munda)
putiputi-nom ir-om luʔr-om
heart-2 beat-2 AUX-2
'your heart is beating'
(Aze, 1973)

Among the more salient phonological features of the Munda languages from a South Asia areal perspective include, in addition to the characteristic 'checked' consonants mentioned above (5), are such areally atypical features of individual Munda languages as low tone in Korku, creaky voice in Gorum, prenasalized stops in Santali, and, unusual syllable structure in Gtaʔ following a series of regular sound changes (seen in such words as Gtaʔ itself).

Munda languages also make extensive use of auxiliary verb constructions. Both a wide range of formal and functional subtypes of auxiliary verb constructions are found across the Munda language family. In general, these are in keeping with both typological and areal norms. Thus, one finds the use of the verb 'eat' in a passive construction found in a number of South Asian languages in such languages as Juang (6). Further, doubled or serialized agreement is found in auxiliary verb constructions in Gorum (7), and is characteristic of local Dravidian languages as well (Parji, Gondi, etc.).

(6) Juang

aiñ ma'd-jim-sɛkɛ	*aiñ ma'd-jim-sɛrɔ*
I beat-eat-PERF.PRES.T	I beat-eat-PERF.PAST.T
'I am beaten'	'I was beaten'
(Pinnow, 1960)	

(7) Gorum
miŋ ne-gaʔ-ru ne-laʔ-ru
I 1-eat-PAST 1-hit-PAST
'I ate vigorously'
(Aze, 1973)

Among present-day researchers of Munda languages, Norman Zide deserves special mention.

Pamela Munro, a prominent figure in the study of American Indian languages, is professor of linguistics at the University of California, Los Angeles, and former president of the Society for the Study of Indigenous Languages in the Americas (2003). She received her Bachelor of Arts at Stanford University, and her Ph.D. in linguistics from the University of California, San Diego, in 1974. She wrote her dissertation on the syntax of Mojave, a language of the Yuman family, spoken along the lower Colorado River near Parker, Arizona. Her primary research focus involves the study of the phonology, morphology, syntax, lexicon, and history of a vast array of languages of the Muskogean, Uto-Aztecan, Yuman, and Zapotecan families. She has published thorough grammars and dictionaries of Chickasaw, San Lucas Quiaviní Zapotec, and Mojave [Mohave], among others. She has also worked on English slang words and expressions used by UCLA students.

Her American Indian dictionaries (generally coauthored with native speakers) and grammars are major contributions to American Indian linguistics. Her Chickasaw dictionary (1994) is the first scholarly dictionary of this language. It contains a Chickasaw-English section with approximately 12 000 main entries and an extensive introductory section describing the structure of Chickasaw words. Chickasaw is a Muskogean language spoken in Oklahoma, where Chickasaws were moved over 150 years ago from their homeland in the southeastern United States. Her *Dictionary of San Lucas Quiaviní Zapotec* (1999) is the first dictionary of the language of this pueblo in Oaxaca, Mexico. It includes Zapotec entries with English and Spanish definitions and English-Zapotec and Spanish-Zapotec indices. She is coeditor and coauthor of *Making dictionaries* (2002),

She received her Bachelor of Arts at Stanford University, and her Ph.D. in linguistics from the University of California, San Diego, in 1974. She wrote her dissertation on the syntax of Mojave, a language of the Yuman family, spoken along the lower Colorado River near Parker, Arizona. Her primary research focus involves the study of the phonology, morphology, syntax, lexicon, and history of a vast array of languages of the Muskogean, Uto-Aztecan, Yuman, and Zapotecan families. She has published thorough grammars and dictionaries of Chickasaw, San Lucas Quiaviní Zapotec, and Mojave [Mohave], among others. She has also worked on English slang words and expressions used by UCLA students.

Her American Indian dictionaries (generally coauthored with native speakers) and grammars are major contributions to American Indian linguistics. Her Chickasaw dictionary (1994) is the first scholarly dictionary of this language. It contains a Chickasaw-English section with approximately 12 000 main entries and an extensive introductory section describing the structure of Chickasaw words. Chickasaw is a Muskogean language spoken in Oklahoma, where Chickasaws were moved over 150 years ago from their homeland in the southeastern United States. Her *Dictionary of San Lucas Quiaviní Zapotec* (1999) is the first dictionary of the language of this pueblo in Oaxaca, Mexico. It includes Zapotec entries with English and Spanish definitions and English-Zapotec and Spanish-Zapotec indices. She is coeditor and coauthor of *Making dictionaries* (2002),

an important work that provides a comprehensive picture of the theory and practice of Native American lexicography and a source for scholars interested in preserving endangered languages.

In 1983 she began collecting a database of slang words and expressions used by UCLA undergraduate students. Every four years she and her students have published a slang dictionary of words and expressions collected during those years. So far she has published four volumes (1989, 1993, 1997, and 2001). Every dictionary reflects cultural changes in American society over the previous four years, with words referring to topics that interest young people away from home for the first time.

In the field of syntax, she has worked on problems of agreement, reference, and subjecthood. She is coeditor and coauthor of *Switch-reference and universal grammar* (1983), in which Munro and other authors analyze the correlation of referential tracking of subjects with particular verbal affixes in several languages. Switch-reference is related to grammatical devices that narrowly define subject identity, such as reflexivation, and devices that broadly define subject identity, such as obviation.

Murayama Shichirô (1908–1993)

A Vovin, University of Hawaii at Manoa, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Shichirô Murayama is an outstanding Japanese linguist and philologist, who specialized in Mongolian, Japanese, Tungusic, Russian, Korean, and Ainu. Born in 1908 in Ibaraki city (Ibaraki prefecture, Japan), a graduate of Waseda University (1931), S. Murayama initially combined his scholarly activities with a career as a journalist and then a diplomat until 1948, when he became a professor at Juntendô University, where he taught German, Latin, and linguistics until 1968, and linguistics at Kyushu University until his retirement in 1972. After retirement, he continued to teach selected courses in linguistics at Kyoto Industrial University until 1981 and at Tokyo Municipal University almost until his demise in 1995. His extraordinarily long and fruitful pedagogical career was combined with no less productive scholarly pursuits, which included active participation in national and international scholarly conferences, research trips, and publication of 16 monographs and approximately 200 articles, reviews, and scholarly reports in Japanese, German, English, and Russian.

S. Murayama's first and last publications dealt with the Ainu language and its history (Murayama, 1944a, 1944b, 1988, 1993, 1995), although he really never left the topic in the middle of his career as well, as his most important publication on Ainu is a study on old sources on Ainu dialects once spoken on Kuril islands (Murayama, 1971). He was under the great influence of the greatest Mongolist of the last century, Nicolaus Poppe, and subsequently Mongolian and Tungusic linguistics, especially Mongolian historical linguistics, became another area where Murayama was very active (Murayama, 1957, 1959a, 1959b, 1962, 1976a). His research on the language of shipwrecked Japanese sailors in 18th-century Russia (Murayama, 1965, 1985), which was a pioneering effort in the sense that it uncovered Japanese dialects as spoken 200 years ago, also led him into the field of Slavic studies (Murayama, 1977). Probably the major research interest of S. Murayama was the genetic affiliation of the Japanese language, which he pursued throughout his life, but especially in the latter part of his career. S. Murayama has published numerous

Shichirô Murayama is an outstanding Japanese linguist and philologist, who specialized in Mongolian, Japanese, Tungusic, Russian, Korean, and Ainu. Born in 1908 in Ibaraki city (Ibaraki prefecture, Japan), a graduate of Waseda University (1931), S. Murayama initially combined his scholarly activities with a career as a journalist and then a diplomat until 1948, when he became a professor at Juntendô University, where he taught German, Latin, and linguistics until 1968, and linguistics at Kyushu University until his retirement in 1972. After retirement, he continued to teach selected courses in linguistics at Kyoto Industrial University until 1981 and at Tokyo Municipal University almost until his demise in 1995. His extraordinarily long and fruitful pedagogical career was combined with no less productive scholarly pursuits, which included active participation in national and international scholarly conferences, research trips, and publication of 16 monographs and approximately 200 articles, reviews, and scholarly reports in Japanese, German, English, and Russian.

S. Murayama's first and last publications dealt with the Ainu language and its history (Murayama, 1944a, 1944b, 1988, 1993, 1995), although he really never left the topic in the middle of his career as well, as his most important publication on Ainu is a study on old sources on Ainu dialects once spoken on Kuril islands (Murayama, 1971). He was under the great influence of the greatest Mongolist of the last century, Nicolaus Poppe, and subsequently Mongolian and Tungusic linguistics, especially Mongolian historical linguistics, became another area where Murayama was very active (Murayama, 1957, 1959a, 1959b, 1962, 1976a). His research on the language of shipwrecked Japanese sailors in 18th-century Russia (Murayama, 1965, 1985), which was a pioneering effort in the sense that it uncovered Japanese dialects as spoken 200 years ago, also led him into the field of Slavic studies (Murayama, 1977). Probably the major research interest of S. Murayama was the genetic affiliation of the Japanese language, which he pursued throughout his life, but especially in the latter part of his career. S. Murayama has published numerous

books and monographs on this extremely complex topic where historical linguists still have no consensus. Although S. Murayama started his research in this area as a scholar advocating Altaic origins of the Japanese language (Murayama, 1957, 1962), in later years he steadily moved in the direction of viewing Japanese as a mixed Altaic-Austronesian language (Murayama, 1974a, 1974b, 1976b, 1978, 1979a, 1979b, 1981a). Although the prevalent view today is that Japanese together with its relative Ryukyuan constitutes a portmanteau family (Japonic), not demonstrably related to any other languages, S. Murayama's main merit lies in establishing a number of important etymologies for Japanese, as well as in uncovering many important internal rules and correspondences in Japanese-Ryukyuan. Also, in a sense, S. Murayama contributed considerably to the theory of mixed languages about 10–15 years before a research on mixed languages surged in Western linguistics. In addition, S. Murayama is famous as a critic of Japanese traditional philology for its weak methodology in comparative linguistics, especially Susumu Ôno's theory of a common origin for Japanese and Tamil (Murayama, 1975, 1981b, 1982). By the breadth of his scholarly interests and importance of his achievements, S. Murayama together with Shirô Hattori and Natsuki Osada, represents one of the three most prolific Japanese linguists of the last century.

Murray, Alexander (1775–1813)

Y Gruntfest, Haifa, Israel

© 2006 Elsevier Ltd. All rights reserved.

The distinguished linguist Alexander Murray was born in Dunkittering, Scotland into a family of shepherds. He learned the alphabet from his father and was only able to attend school irregularly. Thanks to his excellent memory and extraordinary facility in the acquisition of languages, Murray was able, primarily by his own efforts, master Latin, Greek, Hebrew, and French so well that he was admitted to Edinburgh University, where he studied philosophy and divinity. Later he contributed to *Scots Magazine* and the *Edinburgh Review*, writing on different philological and historical subjects. He also prepared the second edition of J. Bruce's *Travels in Abyssinia*. Eventually he became parish minister of Urr. Meanwhile, Murray continued studying languages and acquired substantial knowledge of the spoken tongues of Europe, ancient and new Semitic languages, Persian, and Sanskrit.

In 1812, Murray was elected a professor of Oriental languages in the University of Edinburgh and received the degree of Doctor of Divinity. However, his health was rapidly deteriorating and he died of consumption on April 15, 1813.

In his book *Philosophical history of the European languages*, Murray elaborated a particular theory of historical development of the languages of Europe beginning from the appearance of speech. For the primeval language, he restored nine primary monosyllabic words – *ag*, *bag*, *dwag*, *gwag*, *lag*, *mag*, *nag*, *rag*, and *swag* – which constituted the foundation of language; all other words in European languages developed from them by way of composition, contraction, phonetic changes, and addition of 'consignificative' verbs (future inflexion). This alleged development is illustrated by a profusion of examples.

Murray's theory is characteristic of the transitional period between the Calcutta lecture of W. Jones and the basic works of F. Bopp and R. Rask. It is thoroughly historic and is based on the comparative approach to languages. His wide knowledge of languages allowed the author to use a wealth of linguistic material. On the other hand, Murray set himself unrealistic goals, went too far in his reconstructions, and could not avoid hazardous etymologies and unfounded speculations – two shortcomings against which he persistently warned in the theoretical section of his book.

Murray's book, written from 1805 to 1812, was published posthumously in 1823. It became overshadowed by the tremendous development of the new linguistics and remained on the periphery of linguistic science. A century later, Murray's ideas possibly exerted some influence on the 'Japhetic' theory of N. Marr.

Murray was one of the outstanding lexicographers of the 19th and early 20th centuries. Between 1879 and 1915 he was the Editor, then Editor-in-Chief, of the *New English dictionary on historical principles* (better known as the *Oxford English dictionary*). A man of stamina and strong religious and moral principles, he worked unremittingly on the *Dictionary* for the last 35 years of his life; he did not, however, live to see it completed (in 1928).

He was born into a humble family in Denholm, Scotland, on February 7, 1837. An intellectually inquisitive child, he developed a wide range of linguistic, scientific, and cultural interests – all of which were to stand him in good stead in his later roles as teacher and lexicographer. At the age of 17, he was appointed to a teaching post in one of the schools in the neighboring town of Hawick; this was followed

by the Head Mastership, at the age of 20, of Hawick Academy. The terminal illness of his first wife, Margaret Scott (1834–1865), led to their moving to London in 1865, where he worked as a clerk in one of the London banks. In 1870, he and his second wife, Ada Ruthven (1845–1936), settled in the village of Mill Hill (now a suburb of London) on his appointment as a teacher at Mill Hill School; he remained there until 1885.

While still at Mill Hill, he was appointed editor of the *Dictionary* and took over the responsibility for work that had been carried out fitfully and sometimes inconsistently over the previous 20 years by various members of the Philological Society and their helpers. A modicum of finance for the project was now provided by the Clarendon Press in Oxford. Murray imposed on the work a well-formulated scheme for the collection and analysis of data, based on his assessments of earlier lexicographical methodologies (e.g., those of Samuel Johnson and Noah Webster) and on certain principles of synchronic and diachronic linguistics.

In 1885 the project moved to Oxford, where Murray was to work full-time on the *Dictionary*, helped by groups of readers, research assistants, and members of his own family; the university offered him no teaching post (apart from the Romanes Lectureship in 1900). His own research work, which had included important studies of Scots language and literature (e.g., 1873), had come to a halt with his appointment as editor.

He graduated with a B.A. from London University in 1873. In 1874 he was awarded the honorary degree of LL.D by Edinburgh University; in later years he received honorary degrees from eight other universities. He was knighted in 1908, and died in Oxford on July 26, 1915.

Murray, Lindley (1745–1826)

F Austin, formerly University of Liverpool, Liverpool, UK

© 2006 Elsevier Ltd. All rights reserved.

Lindley Murray (1745–1826), best known for his *English grammar* and as a writer of English school textbooks, trained and had a successful career as a lawyer before he began his work on language. Born into a Quaker family in Pennsylvania in 1745, he was the eldest child of Robert Murray (1721–1786), a merchant and business man. He was educated in Philadelphia and New York but left school at 11 to go into his father's counting house. Unhappy with this work, he studied and subsequently practiced law. In 1767 he married Hannah Dobson (1748–1834) and shortly after, the couple went to England, where he assisted his father in his London business.

In 1771, Murray returned to New York, where he became the scapegoat for the family's involvement in shipping illegal goods during the American Revolution. He went into permanent exile in England, settling in Holdgate near York, where there was a strong Quaker community. It was here that he began his writing career.

Although chiefly known for his books on grammar and the English language, Murray's first publication was a religious treatise, *The power of religion on the mind* (1787). Not until he was fifty, in 1795, did he publish his influential *English grammar*, which was to hold sway for the greater part of the next century. The *Grammar* was quickly followed by *English exercises* and *A key to the exercises* (1797), which were designed to be used in conjunction with the *Grammar;* 1797 also saw *An abridgment of the English grammar* for 'the younger classes of learners.' In 1799, he published *The English reader*, which was particularly popular in America. It was followed by *A sequel to the English reader* (1800) and *An introduction to the English reader* (1801). The *English spelling-book* appeared in 1804, as did *A first book for children*.

Murray was not an original thinker, and his *Grammar* was essentially a compilation from grammars published earlier in the 18th century, as he himself acknowledged. The chief source was Robert Lowth's *Introduction to English grammar* (1762), but Murray

by the Head Mastership, at the age of 20, of Hawick Academy. The terminal illness of his first wife, Margaret Scott (1834–1865), led to their moving to London in 1865, where he worked as a clerk in one of the London banks. In 1870, he and his second wife, Ada Ruthven (1845–1936), settled in the village of Mill Hill (now a suburb of London) on his appointment as a teacher at Mill Hill School; he remained there until 1885.

While still at Mill Hill, he was appointed editor of the *Dictionary* and took over the responsibility for work that had been carried out fitfully and sometimes inconsistently over the previous 20 years by various members of the Philological Society and their helpers. A modicum of finance for the project was now provided by the Clarendon Press in Oxford. Murray imposed on the work a well-formulated scheme for the collection and analysis of data, based on his assessments of earlier lexicographical methodologies (e.g., those of Samuel Johnson and Noah Webster) and on certain principles of synchronic and diachronic linguistics.

In 1885 the project moved to Oxford, where Murray was to work full-time on the *Dictionary*, helped by groups of readers, research assistants, and members of his own family; the university offered him no teaching post (apart from the Romanes Lectureship in 1900). His own research work, which had included important studies of Scots language and literature (e.g., 1873), had come to a halt with his appointment as editor.

He graduated with a B.A. from London University in 1873. In 1874 he was awarded the honorary degree of LL.D by Edinburgh University; in later years he received honorary degrees from eight other universities. He was knighted in 1908, and died in Oxford on July 26, 1915.

Lindley Murray (1745–1826), best known for his *English grammar* and as a writer of English school textbooks, trained and had a successful career as a lawyer before he began his work on language. Born into a Quaker family in Pennsylvania in 1745, he was the eldest child of Robert Murray (1721–1786), a merchant and business man. He was educated in Philadelphia and New York but left school at 11 to go into his father's counting house. Unhappy with this work, he studied and subsequently practiced law. In 1767 he married Hannah Dobson (1748–1834) and shortly after, the couple went to England, where he assisted his father in his London business.

In 1771, Murray returned to New York, where he became the scapegoat for the family's involvement in shipping illegal goods during the American Revolution. He went into permanent exile in England, settling in Holdgate near York, where there was a strong Quaker community. It was here that he began his writing career.

Although chiefly known for his books on grammar and the English language, Murray's first publication was a religious treatise, *The power of religion on the mind* (1787). Not until he was fifty, in 1795, did he publish his influential *English grammar*, which was to hold sway for the greater part of the next century. The *Grammar* was quickly followed by *English exercises* and *A key to the exercises* (1797), which were designed to be used in conjunction with the *Grammar;* 1797 also saw *An abridgment of the English grammar* for 'the younger classes of learners.' In 1799, he published *The English reader*, which was particularly popular in America. It was followed by *A sequel to the English reader* (1800) and *An introduction to the English reader* (1801). The *English spelling-book* appeared in 1804, as did *A first book for children*.

Murray was not an original thinker, and his *Grammar* was essentially a compilation from grammars published earlier in the 18th century, as he himself acknowledged. The chief source was Robert Lowth's *Introduction to English grammar* (1762), but Murray

drew on the work of a number of other grammarians. His originality lay in the design of his books for use in the classroom. All together they provided a complete course for the teaching of English in schools and won immediate popularity. Used for teaching English in countries as far apart as Germany and Japan, the *Grammar* continued to be published until at least 1891 (author's private collection); the *Reader* was published in America until 1856.

The gradual emergence of state education in England during the 19th century may have occasioned the decline in the use of Murray's books. The *Grammar* was certainly used in many private schools and academies (it is referred to in the novels of George Eliot, Dickens, and others), but when the early teacher training colleges began to be set up in the 1840s, these quickly produced their own grammars. Murray's *Grammar* was superseded by those of Allen and Cornwell and Robert Latham. It is unlikely that it was ever much used in the church or state schools to which the majority of the population went. However, many of its precepts concerning 'correct' grammar survive.

Murray's other books were all of a moral or religious nature. An active member of the York Meeting to the end, he died in Holdgate on February 16, 1826.

Musical Semiotics

E Tarasti, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Oddly enough, few of the great semioticians have said anything about music as a sign. Umberto Eco (1968), in his *Struttura assente*, described music as a system having denotation but not connotation, giving the note 'c' as an example. That is all. He touched on music again only in passing, in his essays on number symbolism in the Middle Ages (Eco, 1986). Not one word about music appeared in the massive output of A. J. Greimas or in that of Yuri Lotman. In contrast, Roland Barthes had much to say about music (1975, 1977). A competent pianist himself, Barthes's essay on the 'grain of the voice' remains a classic in studies of vocal expression. Little less quoted but still inspiring are Barthes's ideas on corporeal meanings – 'somathemes,' the smallest units of bodily expression – as they occur in Robert Schumann's piano music.

Claude Lévi-Strauss is a semiotician whose name is almost synonymous with music, which inspired his monumental study of the myths of North and South American Indians (1967–1971). In that study, he introduced his famous model of music and myth, both of which derive from language (**Figure 1**).

His starting point was language as conceived by the Swiss linguist, Ferdinand de Saussure; that is, as a system with units (words) that are divided into two sides: signifier (sound) and signified (sense). For Lévi-Strauss, music was a language without sense (signified), and myth existed independently of its 'sounds' (i.e., the phonemes of the language in which

Musical Semiotics

E Tarasti, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Oddly enough, few of the great semioticians have said anything about music as a sign. Umberto Eco (1968), in his *Struttura assente*, described music as a system having denotation but not connotation, giving the note 'c' as an example. That is all. He touched on music again only in passing, in his essays on number symbolism in the Middle Ages (Eco, 1986). Not one word about music appeared in the massive output of A. J. Greimas or in that of Yuri Lotman. In contrast, Roland Barthes had much to say about music (1975, 1977). A competent pianist himself, Barthes's essay on the 'grain of the voice' remains a classic in studies of vocal expression. Little less quoted but still inspiring are Barthes's ideas on corporeal meanings – 'somathemes,' the smallest units of bodily expression – as they occur in Robert Schumann's piano music.

Claude Lévi-Strauss is a semiotician whose name is almost synonymous with music, which inspired his monumental study of the myths of North and South American Indians (1967–1971). In that study, he introduced his famous model of music and myth, both of which derive from language (Figure 1).

His starting point was language as conceived by the Swiss linguist, Ferdinand de Saussure; that is, as a system with units (words) that are divided into two sides: signifier (sound) and signified (sense). For Lévi-Strauss, music was a language without sense (signified), and myth existed independently of its 'sounds' (i.e., the phonemes of the language in which

Figure 1 Lévi-Strauss's model of music and myth, both of which derive from language. From Lévi-Strauss (1967–1971).

it is told). Given his structuralist frame of reference, Lévi-Strauss thought that everything meaningful originated in language and that when we listen to music we feel an "irresistible" need to fill it with meanings. That is to say, the listener imbues music with sense.

Such a view of musical signs is known as 'musical formalism,' the founder of which was the German musicologist and critic, Eduard Hanslick. In his essay, *Vom musikalisch Schönen* (1854), Hanslick defined music simply as *tönend bewegte Formen*, 'moving aural forms.' Igor Stravinsky (1956) later rearticulated this view in his Harvard lectures, saying that music had no place for the subjective; it only had to be played. This practical view is shared by many other musicians who refuse to discuss their skills or craft.

This practical view evokes one basic distinction within musical semiotics and concerns the very possibility of the existence of such a discipline, as a part of semiotics, on the one hand, and as a part of musicology, on the other. The formalist standpoint is that music is an a-semantic art, unable to convey any kind of meanings. The acceptance of the contrasting view – that music contains meanings – opens the avenue for musical semiotics in the proper sense. Yet, even there we have a variety of theoretical positions:

- Music *represents* (i.e., musical signs stand for something). This view is shared by scholars who apply Peirce's semiotics to music. Vladimir Karbusicky (1986) attempted to do so in his *Grundriss der musikalischen Semantik,* the seminal work of Peircian applications to music.
- Music *signifies* (i.e., musical signs are their own special type of language). We can approach the problem of meaning in the Saussurean tradition by saying that there are at least two levels of meaning in musical semiotics with corresponding units: syntactic and semantic entities, phonemes and sememes, or first articulation units (words) and second articulation units (phonemes; Andre Martinet's classifications). Most of the work done in musical semiotics during the previous decades has followed this line of thinking.
- Music *expresses* (i.e., music has a relationship to emotions). Susanne Langer (1942) said that musical is a logical symbol of the emotions, or consider these terms proposed by other scholars: referential/embodied meanings of music (Meyer, 1973), intrageneric/extrageneric meaning (Coker, 1972) and even the existential semiotic view by Eero Tarasti (endogenin/exogenic signs; 1979) referring as well to A. J. Greimas' s distinction between interoceptive/exteroceptive semiotic categories. In contrast, the British esthetician Roger Scruton denied the language-likeness of music. He proposed that musical meanings are always due to extra-musical association evoked by the titles and programs; for example, if Debussy's 'La Mer' would not have had that title, it could be taken as a portrayal of a forest fire or anything else.

All these positions are related to another one, particularly in terms of musical signs, namely their notation. It is somewhat surprising how few scholars have pondered notation as a truly semiotic problem: Do traditional musical notations have their own syntax and semantics? Charles Seeger (1977) distinguished between two kinds of notation: prescriptive and descriptive. Notation is prescriptive if one is able to perform the music from the signs; descriptive notation only describes music in some respect, but does not lead into a performance. Most of the analyses done in musical semiotics belong to the latter category.

However, when considering the first historic phases of the Western *eruditem usic notation* – namely, the creation of neume writing of the Gregorian plain chant – we already encounter truly semiotic problems. Leo Treitler discussed these issues in the Peircian framework in his recent study, *With voice and pen* (2003). Regarding neumes that represent pitch and time of a melodic line, he wrote, "The philosopher Charles Peirce provided useful and influential conceptual apparatus for the analysis of the functioning of signs in terms of their modes of representation" (Treitler, 2003: 330). Yet, he then asked, "How did the early writers and readers of music conceive of what it was that their notations signified?" The problem goes further: Does traditional notation also represent semantics (i.e., is it a semiotic system in *that* sense?). Willi Apel has pointed out in his *Notation der polyphonen Musik* that the red and black neume writing signified that those notes were to be performed three times faster than other ones. This means that the kinetic energy of music changed. Here, we can already see a tiny marginal semanticism on purely musical terms.

Precursors of Semiotic Analysis of Music

In the area of music theory and analysis, German-speaking academe produced two remarkable music scholars who may be considered protosemioticians: the Austrian Heinrich Schenker (1868–1935) and the Swiss Ernst Kurth (1886–1946). According to Schenker (1956), the great composers improvised their musical works out of a deep structure that he called *Ursatz* (the resonance of the term with Goethe's *Urpflanz* is not coincidental). He distinguished three

level of musical generation: background, middle ground, and foreground (see Neumeyer, 1988 and a deconstructionist interpretation of Schenker by Littlefield, 2001). The merit of this 'structuralist' idea was that every musical event was significant and had its right place. Temporally separated tonal events formed a part of *Urlinie*. Hence, the method also accounted for the fundamentally kinetic nature of music. After his death, his model became dominant in the United States.

When musicologist Fred Lerdahl and linguist Ray Jackendoff published their work, *A generative theory of tonal music* (1985), it became obvious that Schenker's model was very similar to Noam Chomsky's 'Tree Model' of linguistic phrase structure. Yet, in fact, Leonard Bernstein (1976) in his *The unanswered question* was the first to suggest the parallel between generating a piece of music and a linguistic utterance. As early as the 1960s, semioticians had proposed that language and music were analogous phenomena because they both consisted of chains of acoustic signals (cf. Posner, 1988).

In contrast, Ernst Kurth's 'energetic' conception of music has only been considered a precursor of musical semiotics. His views have proved particularly useful as a counterbalance to the segmentational and taxonomic methods of semiotic music analysis in the 1980s. Kurth (1922) stressed the energetic, continuous nature of music and not the separate, discrete signifiers – the signs perceived by the auditory sense. What mattered for Kurth was the signified, the kinetic energy pulsating behind the notes. He even spoke of notes as having "a will to a chord." In this sense, he joined the philosophical epistemes at the turn of the century; for example, Henri Bergson's (1975) view of two kinds of time: *temps d'espace* (space time), which could be physically measured, and *temps de durée* (duration), which was phenomenal, experienced time. Kurth also emphasized the temporal nature of music; for him, the pertinent aspect in music was the experience of movement as he stated in his *Grundlagen des linearen Kontrapunkts* (1922), a study of J. S. Bach's melodic style.

Thus, Kurth can be considered a semiotician in three senses. He taught (1) that the sound stimulus of music always functions as a sign for something (semantics), (2) that attention must be paid to what happens in the mind when one is listening to music (cognition), and (3) that analysis starts 'inside' and moves toward the 'outside'; that is, from deep structure to the surface (a structuralist and generativist approach). Kurth did not develop an explicit analytic procedure, though his theories always remained closely connected to musical practice; for example, his treatise *Romantische Harmonik and ihre Krise* (1923) dealt with Wagnerian chromaticism, and his most extensive analyses were of Bruckner's symphonies (1925).

On the basis of language inflection and of Kurth's theories, Boris V. Asafiev (1884–1948) developed his intonation theory, which became the prevailing theory and analytic method in Eastern Europe for decades after World War II. Asafiev was a prolific writer who also published under the pseudonym, Igor Glebow. His main work, *Musical form as a process*, translated into English in 1977, launched his basic concept of 'intonation,' which paired any musical element – interval, chord, rhythm, motive, timbre – with its emotional value or content. In its aim to unite musical signifiers and signifieds, this theory was inherently semiotic. He also emphasized the mobile character of music and presupposed that intonations formed chains of functions, such as *initium* (beginning), *motus* (movement), and *terminus* (ending, cadence). He hypothesized that 'stores' of intonation are formed from characteristic musical passages and that these repositories of intonations remain in the collective memory of listeners. These stores contain the bases of the way people feel in a given period, such that music could be sensed as 'true speech.' When people's thinking changes, new intonations arise. Asafiev studied such an intonation crisis in connection with the French Revolution.

In the West, Asafiev remained almost completely unknown until music semioticians in the 1970s rediscovered his work. His theories were adapted to modern narratology by Viatcheslaw W. Medushewski, who distinguished between protointonation – an expressive shape, such as a cry or exclamation, without any compositional articulation – from musical intonation in the proper sense. In Russia, Asafiev's theories were applied further by Joseph Kon, Yury Kholopov, and Yevgeny Nazaikinsky, and they have influenced the work of Jaroslav Jiranek – for example, his *Grundfragen der musikalischen Semiotik* (1985) – and of the Hungarian academician Jozseph Ujfalussy (e.g., 1968). Moreover, some present-day studies of popular music reflect the influence of Asafiev, as in the theory of 'hooks' of popular song (Frith, 1978, 1984.) and the 'affect analysis' of popular music by Philip Tagg (1979).

In the United States, as a precursor of modern ethnomusicology, Charles Seeger (1960) pondered deeply the semiotic problems of music, and it is unfortunate that his epoch-making essay, 'On the moods of a music logic', was left out of discussions of musical semiotics in the 1960s and 1970s. In that essay, Seeger presented a structuralist model of analysis in which various musical parameters are divided into their smallest units, called 'moods,' which can be

combined into larger entities. Seeger (1977) also studied the semiotic nature of transcription in ethnomusicology as a prescriptive or descriptive procedure and dealt with issues of value in music.

The term 'semiotics' rarely appeared in Leonard B. Meyer's extensive work in music analysis and esthetics, though he nevertheless dwelt on semiotic problems, such as the distinction between referential and embodied meanings. Meyer's most outstanding analytical work is *Explaining music* (1973), in which he presented a model of analysis based upon the concept of implication. Susanne K. Langer (1895–1985) was among the foremost American semioticians (cf. Sebeok, 1991), but her musical esthetics, advanced in her book *Philosophy in a new key* (1942), is rarely mentioned in connection with musical semiotics. According to Langer, music does not present symptoms (indexical signs) of feelings, but rather their 'logical expression' (symbols).

In Europe, it is often hard to distinguish traditional musicologists from semioticians of music. A typical example was the Swede Ingmar Bengtsson, who began his career as a music historian and style analyst and only later became interested in musical semiotics and nonverbal communication (see Bengtsson, 1973).

Main Lines in the Development of Musical Semiotics

Musical semiotics, as a field relatively independent of both semiotics and musicology, started to develop as early as the 1950s and 1960s. Like general semiotics in those days, musical semiotics was structuralist in its strong allegiance to linguistic models.

The first noteworthy application of linguistics to music was Nicolas Ruwet's (1972) studies of the interrelationships of language and music, and particularly his analyses of the prelude to Debussy's *Pelleas* and of medieval *Geisslerlieder.* Reading a myth as one would read a musical score – an idea borrowed from Lévi-Strauss's (1958) analysis of the Oedipus myth and now turned back to music – Ruwet invented the paradigmatic method of analysis. Similar musical motives were placed in a chart one under the other so that one could see at a single glance their distribution in a whole piece of music. From the beginning, the problem of singling out paradigmatic units received much emphasis, and criteria by which to carry out segmentation were discussed at length. Jean-Jacques Nattiez (1975, 1990) adopted distributional analysis from Ruwet and established it for a long time as *the* music–semiotical analytic method. The model example of Nattiez's paradigmatic method is his analysis of Debussy's Sy*rinx*.

The paradigmatic method aimed to derive a generative grammar for musical texts. Focusing on the styles of some relatively restricted and simple musical works, one could formulate generative rules by which new, style-coherent, grammatically well-formed melodies could be produced endlessly by a computer; in a test situation, the computer-produced melodies were indistinguishable from the 'authentic' melodies. Such applications were performed on children's songs in Germany by Thomas Stoffer (1979); in Sweden by Johan Sundberg (1992), Sundberg and Lindblom (1970); in Italy by Mario Baroni and Franco Jacoboni (1978), Rossana Dalmonte (1981) on Bach's chorales and Legrenzi's arias, and later by Lelio Camilleri (1992); in Canada by Ramón Pelinski (1981) and by Jean Jacques Nattiez on the music of the Inuits; and in Finland by Erkki Pekkilä (1988) on folk music.

Nattiez improved his paradigmatic model by recasting the musical message or text itself as the 'neutral level,' to which he added the levels of creation (poiesis) and reception (esthesis), which altogether comprise what Jean Molino (1975) called the "total musical fact." In addition to musical production and reception, musical semiotics also had to clarify the implicit criteria used in the paradigmatic analysis itself. Nattiez's own analysis of Wagner's 'Tristan chord' and its various interpretations well illustrated this strategy (1990: 216–238). Nattiez applied his tripartite model to Chéreau's and Boulez's Wagner interpretations (1983) and then improved it considerably in his *Musicologie générale et sémiologie* (1987) and *Music and discourse* (1990).

The First International Congress on Musical Semiotics, held in Belgrade in 1973 and organized by Gino Stefani and others, brought attention to a whole group of such musical semioticians. Many of them fit the profile of a traditional musicologist, to whom semiotics came more or less naturally. For example, Stefani, the leading contemporary Italian semiotician of music, was influenced by his education in Catholic liturgical music and music of the Baroque era. In his numerous works (e.g., 1974, 1976, 1977, 1982; Stefani *et al.,* 1990), Stefani remained close to the everyday practices of music. He wanted to develop a musical semiotics that could be used in music education, music therapy, and cultural animation. His theoretically most cogent work, *La competenza musicale* (1982), was based upon the distinction between two models of musical competence: popular and erudite. The model contained five levels altogether – work, style, musical techniques, social practices, and general codes – that are present to varying degrees in the aforementioned competences. Lately, Stefani and his wife Stefania Guerra Lisi developed a new approach to the application of semiotics, based on the 'globality

of languages,' understood as musical universals of prenatal origin. Pupils of Gino Stefani, such as Luca Marconi, Marco Beghelli, Dario Martinelli and Francesco Spampinato, have become influential among the younger generation of music semioticians.

From a very different direction came the musical semiotics of two Czech scholars, Jaroslav Jiranek and Vladimir Karbusicky, both of whom have a structuralist background. Whereas Jiranek leaned more toward Asafiev's intonation theory (and earlier, the Marxist model), Karbusicky chose Peirce's sign theory as his starting point. Karbusicky's *Grundlagen der musikalischen Semantik* (1986), one of the most essential readings in the field, was based upon Peirce's concepts of icon, index, and symbol. He considered music to be an indexical expression of emotions and has conducted experimental studies in musical meaning to prove this assumption.

Peirce's theory has also been applied to music by the Canadian David Lidov (1980) and the American Robert S. Hatten (1987), who also developed a theory of markedness in his analyses of Beethoven (1994). Hatten's ideas on style and strategy were particularly noteworthy in his studies that aimed to unite the semiotic approach with a detailed style analysis of classical composers. Recently, Hatten has focused on gestures in music. Wilson Coker (1972), William Dougherty (1993), Kofi Agawu (1991), David Mosley, and Naomi Cummings also have followed this approach. Lewis Rowell has studied a.o. the musical time.

Polish scholars have made important contributions to musical semiotics in Eastern Europe; they include Mieczyslaw Tomaszewski, who has developed a highly original semiotic–hermeneutic approach in his Chopin studies; Michal Bristiger in his researches in music history; Anna Czekanowska in ethnomusicology; and the younger scholars, Danuta Mirka and Maciej Jablonski.

A special school of musical semiotics sprang from the theories of the Lithuanian-born semiotician, Algirdas Julien Greimas. Eero Tarasti (1979) applied his *semanalyse* to mythical meanings in music, trying to show that the interaction of myth and music, in Lévi-Strauss's sense, has also taken place in the context of Western music. Tarasti's later narratological inquiries – mainly based on Greimas but also using concepts drawn from the theories of classical semiotics – have dealt both with programmatic and absolute music. His theory of musical semiotics is based upon four phases chosen from Greimas's generative course: (1) isotopies; (2) spatial, temporal, and actorial categories and their engagement/disengagement; (3) modalities; and (4) semes/phemes. Perhaps, the most important and original of these levels is the one dealing with musical modalities: 'will, know, must, can, and believe.' These modalities, which originated in linguistic–semiotic theories, can be defined in purely musical terms as well (see Tarasti, 1992d, 1994a).

Other scholars, too, have applied Greimas's concepts to music. For example, Ivanka Stoianova (1978) developed an original theory combining psychoanalysis, intonation theory, and semiotics. Márta Grabócz (1986), a Hungarian musicologist and student of Jozseph Ujfalussy, applied the concept of isotopy to Liszt's piano music and to electronic compositions. Especially noteworthy are her studies of electronic music by François-Bernard Mâche (Grabócz, 1991–1992). Remarkable music semioticians in Strassburg University around Grabócz are Xavier Hascher and Beat A Foellmi.

Moreover, Greimas's method still prevails in his homeland Lithuania, in Southern Europe, and in Latin America. Daniel Charles is one of the outstanding music philosophers of France, specializing in Heidegger, on the one hand, and on John Cage's Zen philosophy, on the other. His recent works have a strong semiotic relevance. Greimas's pupil, composer Costin Miereanu, now a professor in Paris I, has maintained the Greimassian approach in his theoretical writings. Furthermore, Greimas has inspired other younger scholars, particularly those at Aix en Provence, where one finds such scholars as Bernard Vecchione (1986, 1987), the music sociologist Jean-Marie Jacono, Christine Esclapez, and Christian Hauer.

In ethnomusicology, semiotic ideas have been used by such scholars as John Blacking, who studied the musical semantics of South African Veda music in his *How musical is man?* (1976). Charles Boiles clarified how meanings were united with music by the Tepehua Indians (1973). Simha Arom has studied the music of the pygmies (1969). Erkki Pekkilä (1988) has focused on music and media, as well as on rural Finnish musical styles. Together with North and South American scholars, Pekkilä is leading an international research project on music and media. Yoshihiko Tokumaru (1980) has applied semiotics to Japanese traditional music, and Shuhei Hosokawa (1981) has investigated contemporary Japanese culture, as in his analysis of the Walkman. Also notable in Japan is the teaching and theoretical work of Satoru Kambe in Tokyo.

Raymond Monelle (1992) of Edinburgh, in his *Linguistics and semiotics in music*, provided an overview of musical semiotics in all its breadth to British academe, though as early as the beginning of the 1980s, nearly all the most important introductions to music analysis published in the Anglo-Saxon world already contained at least one chapter on musical semiotics (cf. Bent, 1987; Dunsby and

Whittall, 1988). Monelle's (2000) study, *The sense of music*, applied deconstructionist ideas to music. Most recently Monelle has studied the theory of musical topics. Younger scholars have focused on these areas: Michael Spitzer at Durham University on the interrelationships of music and arts in his recent study on musical metaphors; Nicholas McKay on style analysis following Hatten's model; and Tom Pankhurst on further developments of Schenker's theories.

The most extensive research project in musical semiotics being conducted today is entitled 'Musical Signification.' It includes about 450 scholars from all over the world, bringing together music semioticians of all stripes, both traditional musicologists and ethnomusicologists, computer theoreticians, cognitive scientists, psychoanalysts, historians, and many other music researchers. The project was founded in Paris in 1985 by a group of scholars including François Delalande, Costin Miereanu, Marcello Castellana, Gino Stefani, Luiz Heitor Correa de Azevedo, and Eero Tarasti, who has directed it since then. So far, it has held eight international congresses: in 1986 in Imatra, 1988 in Helsinki, 1990 in Edinburgh, 1993 in Paris, 1995 in Bologna, 1998 in Aix en Provence, in Imatra again in 2001, and in Paris again in 2004. The papers of these symposia have been published by various international and academic publishing houses (among others, see Tarasti, 1996; Miereanu and Hascher, 1998; Stefani *et al.,* 1998). Anthologies and papers from the doctoral seminars are regularly published in the series *Acta Semiotica Fennica* by the International Semiotics Institute at Imatra, in collaboration with Indiana University Press.

This project has become the world's largest gathering of music semioticians and has contributed to establishing this new discipline in colleges and universities around the globe. It also includes an international doctoral and postdoctoral seminar that is organized annually at the University of Helsinki. In these seminars, training is given to future doctors in musical semiotics.

Musical semiotics has also expanded into Latin America. For example, José Luiz Martinez, who received his doctorate from the University of Helsinki, has focused on musical semiotics in Brazil – to which we have to add the work of Heloísa Araújo de Duarte Valente, Edson Zampronha and Maria Louisa Zekeff, Lia Tomas, and others. In Mexico, seminars have been held at UNAM in Mexico City by Susanna Gonzalez Aktories, Mario Stern, Ruben Lopez Cano who is now in Spain, and others.

Present Trends: From Biosemiotics to Existential Semiotics

During the last 30 years musical semiotics has become part of 'normal' musicology. At the same time, it has gained its freedom from the control of general semiotics and has focused on the autonomy and originality of musical discourse. Recently, semiotics has become one of the branches of cognitive studies, which investigates the counterparts of musical processes in neural network models of the human brain.

More and more, there is a general tendency to abandon the simple generative models of rules for linear configurations in a search for new types of theoretical schemes. This trend has been encouraged by results in the semiotics of other fields, such as deconstructionism, psychoanalysis, feminist studies, critical studies, and so on. On the American scene, musical semiotics has been appropriated by the so-called new musicology. This field includes a.o. psychoanalytically and gender oriented studies, which often come close to semiotic reflections. One may even speak of the 'emancipation of musical signs,' which has delivered American scholars from their earlier, rigidly positivist models and led them to more interpretative and hermeneutic reflections. Thus, Richard Taruskin (1997) has adopted the concept of the semiotic from Kristeva (1969), and Marianne Kielian-Gilbert (1987) has applied it to feminist musicology. However, without the theoretical groundwork laid by semioticians, these important applications would not have been possible.

Many scholars (e.g., Imberty, 1976, 1981) who practiced semiotics in the area of experimental psychology of music have quite naturally ended up in the cognitive sciences. One of the leading scholars in this field with close ties with semiotics is Mark Reybrouck. Conversely, one can consider the cognitive approach as but a subdiscipline of semiotics. It is in fact a rather recent invention, when viewed in light of the 2000-year history of semiotics in Western civilization.

Quite new paradigms have also been devised in musical semiotics recently. One is the school stemming from biosemiotics, established in the 1940s by the Estonian biologist Jakob v. Uexküll (1940) and rediscovered by Thomas A. Sebeok and colleagues in the 1990s. The central idea of a living organism in an interaction with its surroundings or *Umwelt* was elucidated by the principle of *Ich-Ton,* a kind of code or inner principle that decides which signs an organism accepts from its surrounding and which it rejects. According to Uexküll, the organism seemed to function on the basis of an inner 'score' that guides its activities, signifying and acting (*Merken und Wirken)*. This principle could be brought back to music by assuming that each composer and each single music work have its own particular 'Me-Tone' that decides which musical signs are adopted from its musical environment and tradition

and which are excluded. Biosemiotics leads to the discussion of the metaphor of musical organism or what makes music organic. In music, biosemiotics is the term for the zoomusicology of Francois-Bernard Mâche to Dario Martinelli (2002).

Another new approach is the existential semiotics of Eero Tarasti (see Tarasti, 2000 and the special issue of 'Degres, Sémiotique existentielle,' 2003). It aims for a radically new epistemology of semiotic theories, and hence ultimately a new application to music analysis. This new philosophy is inspired by German, Danish, and French philosophers from Hegel to Kierkegaard, from Heidegger to Jaspers and Sartre, and launches new concepts as *Dasein* and transcendence. Yet, it is in no way any return to existentialism. Rather, it strives to examine the life of the signs as processual entities, from the inside. Quite a deal of new sign categories have been discovered in the dialectics between *Dasein* and transcendence: presigns, actsigns, postsigns, transsigns, quasisigns, endo- and exosigns, and pheno- and genosigns. Using these tools, one can better explain the nature of music as a temporal and dynamically forming art. Scholars working in this field include Daniel Charles, Drina Hocevar (Venezuela; see Hocevar, 2003), Maciej Jablonski (Poland), and others.

In any case, semioticians of music are no longer outsiders, neither in general semiotics nor in musicology. The field of musicology has in fact tacitly adopted many concepts introduced by semioticians, such as the distinction between the subject of the enunciate and that of the enunciation (Dahlhaus made this distinction, erroneously thinking he had borrowed it from the Russian formalists).

There have been several publishing venues for musical semiotics. The journal *Musique en jeu,* in which Nattiez published his first articles, was such a venue in the 1970s. Later, music semioticians had to publish their essays either in general musicological journals, such as IRASM, *Analyse musicale, Music Theory Spectrum, Indiana Theory Review, Music Analysis,* and the like, or in semiotic journals; on the latter, see the special issues on the semiotics of music in *Semiotica* (1976 and 1987), *Zeitschrift far Semiotik* (1987), and *Degrés* (1987–1988). *Eunomio*, edited by the Italian musicologists Paolo Rosato and Michele Ignelzi, is devoted totally to the semiotic analysis of music. Nevertheless, the number of dissertations underway in many parts of the world, the increasing number of new books on the subject, and the widening variety of theoretical approaches available to scholars working in the field show that musical semiotics is continuing to grow both in quantity and quality.

Muskogean Languages

G A Broadwell, SUNY – Albany, Albany, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Muskogean languages were originally spoken across much of the southeastern United States, from Georgia to Louisiana. As a result of population movements, both voluntary and forced, many speakers of Muskogean languages are now located outside the original Muskogean-speaking area. More than half of the speakers of Muskogean languages now live in either Oklahoma or southern Florida.

There are six different Muskogean languages that are still spoken.

1. Choctaw is the largest Muskogean language, with perhaps 7000 to 11 000 speakers divided between the Mississippi Choctaw reservation in eastern Mississippi and the Oklahoma Choctaw nation of southeastern Oklahoma.
2. Chickasaw is spoken by a few hundred people in the Chickasaw nation of southern Oklahoma.
3. Alabama is spoken by a few hundred people on the Alabama-Coushatta reservation in eastern Texas.
4. Koasati (also called Coushatta) is spoken by a few hundred people in the area around Elton, Louisiana, and by a smaller number (probably fewer than 50) on the Alabama-Coushatta reservation.
5. Mikasuki (also spelled Miccosukee) is spoken by approximately 1000 people in the Seminole and Miccosukee tribes of Florida, located in the Everglades region of Florida.
6. Creek (also called Muskogee or Muscogee) is spoken by approximately 4000 people. The great majority of these speakers live in the Muscogee (Creek) Nation of Oklahoma and in the Seminole nation of Oklahoma. There are perhaps 200 speakers of Creek in the Seminole tribe of Florida.

'Seminole' is a term that is potentially confusing. It refers primarily to a political grouping of Creek and Mikasuki speakers who moved from their former territory in Georgia and Alabama to new locations in south Florida beginning in the mid-18th century. During the Indian removal period of the 1830s, many Seminoles were forcibly resettled in Oklahoma, so that there is now both a Seminole Nation of Oklahoma and a Seminole tribe of Florida.

Oklahoma Seminoles who retain their native language speak a dialect of Creek called Oklahoma Seminole Creek. Florida Seminoles speak two different languages – the majority speak Mikasuki and a minority speak a dialect known as Florida Seminole Creek.

In addition to these six languages, three other extinct Muskogean languages are attested:

7. Apalachee was spoken by inhabitants of northwest Florida. The language is attested in a 17th century letter to Charles II of Spain, but has long been extinct.
8. Hitchiti was a language that seems to have been quite similar to Mikasuki. It was spoken

Muskogean Languages

G A Broadwell, SUNY – Albany, Albany, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Muskogean languages were originally spoken across much of the southeastern United States, from Georgia to Louisiana. As a result of population movements, both voluntary and forced, many speakers of Muskogean languages are now located outside the original Muskogean-speaking area. More than half of the speakers of Muskogean languages now live in either Oklahoma or southern Florida.

There are six different Muskogean languages that are still spoken.

1. Choctaw is the largest Muskogean language, with perhaps 7000 to 11 000 speakers divided between the Mississippi Choctaw reservation in eastern Mississippi and the Oklahoma Choctaw nation of southeastern Oklahoma.
2. Chickasaw is spoken by a few hundred people in the Chickasaw nation of southern Oklahoma.
3. Alabama is spoken by a few hundred people on the Alabama-Coushatta reservation in eastern Texas.
4. Koasati (also called Coushatta) is spoken by a few hundred people in the area around Elton, Louisiana, and by a smaller number (probably fewer than 50) on the Alabama-Coushatta reservation.
5. Mikasuki (also spelled Miccosukee) is spoken by approximately 1000 people in the Seminole and Miccosukee tribes of Florida, located in the Everglades region of Florida.
6. Creek (also called Muskogee or Muscogee) is spoken by approximately 4000 people. The great majority of these speakers live in the Muscogee (Creek) Nation of Oklahoma and in the Seminole nation of Oklahoma. There are perhaps 200 speakers of Creek in the Seminole tribe of Florida.

'Seminole' is a term that is potentially confusing. It refers primarily to a political grouping of Creek and Mikasuki speakers who moved from their former territory in Georgia and Alabama to new locations in south Florida beginning in the mid-18th century. During the Indian removal period of the 1830s, many Seminoles were forcibly resettled in Oklahoma, so that there is now both a Seminole Nation of Oklahoma and a Seminole tribe of Florida.

Oklahoma Seminoles who retain their native language speak a dialect of Creek called Oklahoma Seminole Creek. Florida Seminoles speak two different languages – the majority speak Mikasuki and a minority speak a dialect known as Florida Seminole Creek.

In addition to these six languages, three other extinct Muskogean languages are attested:

7. Apalachee was spoken by inhabitants of northwest Florida. The language is attested in a 17th century letter to Charles II of Spain, but has long been extinct.
8. Hitchiti was a language that seems to have been quite similar to Mikasuki. It was spoken

in Florida and Oklahoma until the early 20th century.

9. Mobilian Jargon (Mobilian) was a Muskogean-based trade language spoken in the lower Mississippi Valley. Some fragments of the language were spoken by a few people in Louisiana until the 1970s.

Classification

The currently spoken Muskogean languages fall into the following groups:

Kimball and Haas have argued that the extinct language Apalachee was most closely connected to Alabama and Koasati.

Higher level classification of the Muskogean languages is difficult and a subject of controversy. Based on several identifiable sound changes, Haas proposed that Alabama, Koasati, Mikasuki, and Creek formed a group called Eastern Muskogean. However, another subsequently discovered sound change (Proto-Muskogean $*k^w \rightarrow b$) supports a rather different grouping, in which Western Muskogean, Alabama, Koasati, and Mikasuki form a group called Southern Muskogean (affected by the $*k^w \rightarrow b$ rule). This group is distinct from Creek, which was not affected by this rule. Munro and Broadwell have also presented morphological evidence in favor of a Southern Muskogean group. There is as yet no consensus on this issue.

Phonological Characteristics

Muskogean languages have relatively simple phonological inventories. Choctaw and Chickasaw, for instance, have an inventory of 16 consonant phonemes (Table 1).

In addition, all Muskogean languages have three phonemic vowels /a, i, o/ that appear short, long, and nasalized.

Muskogean languages have pitch-accent. In verbs, the position of pitch accent is generally dependent on the 'grade' in which the verb appears. Grades are a series of related verb forms that differ in tense and/or aspect from each other, and that are formed by infixing a consonant or consonants, lengthening a vowel, or changing the form and position of the pitch accent. Consider the following examples from Creek:

Table 1 Choctaw and Chickasaw consonant phonemes

Bilabial/ Labiodental	*Alveolar*	*Postalveolar/ Palatal*	*Velar*	*Glottal*
p	t	tʃ	k	ʔ
b				
f	s	ʃ		h
m	n			
	l			
	ɬ			
w		j		

/ʔ/ in most Choctaw dialects is restricted to word-final position, while it has a wider distribution in Chickasaw.

(1) Creek
wanáj-as [wanáyas] 'tie it!'
underived grade
wana<:>j-ís [wana:jís] 's/he is tying it'
lengthened grade
waná<h>j-is [wanáhjis] 's/he tied it (today, last night)'
aspirated grade
wanâ<:>j-is [wanâ:jis] 's/he has tied it.'
falling-tone grade
wanǎ<:˜>j-is [wanǎ:jis] 's/he keeps tying it.'
nasalizing grade

In these examples, the lengthened grade is associated with eventive aspect, the aspirated grade with the perfective aspect, the falling tone grade with the stative perfective aspect, and the nasalizing grade with the expressive grade (a grade expressing a large degree of something, sometimes equivalent to a continuative).

The infixed material or vowel length change in a grade appears in the syllable that is historically the penult of the verb stem. This continues to be the location of infixation and lengthening in Western Muskogean, Alabama, and Koasati. Due to loss of final vowels in Creek and Mikasuki, these changes now affect the final syllable of the verb stem.

For the purposes of calculating the final or penultimate syllable of the verb stem, all Muskogean languages need to make a distinction between those suffixes after the verb root that count as inside the stem ('stem-forming suffixes') and those that count as outside the stem ('non-stem-forming suffixes'). For example, in the following Creek examples, the plural suffix /-ak-/ is a stem-forming suffix, but neither the indicative /-is/ nor the second-person singular Agentive suffix /-ítʃk-/ counts as stem-forming:

(2) Creek
wanaj-á<h>k-is.
tie-PLUR<PERF>-INDIC
'They tied it (today/last night).'

waná<h>j-ítʃk-is
tie<PERF>-2.SING.AGENT-INDIC
'You tied it (today/last night).'

Some suffixes may require that the preceding stem appear in a particular grade. The negative suffix /-o/ in Chickasaw, for example, must appear with the preceding verb in the glottal grade, which infixes a glottal stop in the penult of the stem.

Morphosyntactic Characteristics

All Muskogean languages show verb morphology of the agent/patient (or 'active') type, where verbs show different types of subject and object agreement based on the semantic roles of their arguments. In Choctaw, for example, intransitive verbs fall into three types: one type uses a morphology we can refer to as Agentive agreement, another uses Patientive agreement, and a third type uses Dative agreement:

(3) Choctaw
Tolo:wa-li-tok.
sing-1.SG.AGENT-PAST
'I sang.'
Sa-lakʃa-tok.
1.SG.PATIENT-sweat-PAST
'I sweated.'
Am-ihaksi-tok.
1.SG.DATIVE-forget-PAST
'I forgot.'

The Dative agreement type is primarily used for the subjects of some verbs of cognition and emotion in Choctaw. In addition to these types, there is also a distinct set of Agentive prefixes with negative subjects.

Although there are clear semantic generalizations about the agreement type, the system is partially lexicalized, and verbs with similar semantics may take different types of agreement:

(4) Choctaw
Sa-yimmi-tok.
1.SG.PATIENT-believe-PAST
'I believed.'
Anokfilli-li-tok.
think-1.SG.AGENT-PAST
'I thought.'

There are other areas of irregularity in the system as well, such as the fact that quantificational verbs (e.g., 'be all') take Agentive agreement in all the Muskogean languages.

Despite the existence of active verb agreement morphology, overt noun phrases are case-marked on a nominative-accusative basis, and all subjects receive nominative case, regardless of what type of agreement they trigger.

Consider the following Choctaw examples:

(5) Choctaw
An-ako:ʃ John(-ã)
I-CON.NOM John(-ACC)
ahpali-li-tok.
kiss-1.SG.AGENT-PAST
'I kissed John.'

An-ako:ʃ John(-ã)
I-CON.NOM John(-ACC)
sa-nokʃopa-tok
1.SG.PATIENT-fear-PAST
'I was afraid of John.'

In these examples, both subjects receive obligatory nominative case, though one triggers Agentive agreement and the other triggers Patientive agreement. Accusative case marking is optional in Choctaw.

Although the division among different agreement types is complex, the morphology itself is fairly regular in Western Muskogean, Mikasuki, and Creek. Mikasuki and Creek have suffixed forms of the Agentive agreement markers and prefixed forms of the Patient and Dative agreement markers. In Western Muskogean, all the agreement markers are prefixes, with the single exception of the first-person singular Agentive suffix /-li/. Though verbs vary in which type of agreement markers they use, the placement of these agreement markers is consistent across these languages.

In Alabama and Koasati, however, the situation is much more complex, with prefixed, suffixed, and infixed agreement markers. Consider, for example, the affirmative conjugation of the verb /ó:tin/ 'to gather' in Koasati:

(6) Koasati

ó:ti-1	'I gather'
ó<s>ti	'You gather'
ó:t	'She/he/they gather'
ó<l>t	'We gather'
ó<has>t	'You (pl.) gather.'

Kimball's grammar of Koasati identifies 10 distinct conjugation subclasses based on the identity and position of the agreement morphology, with membership in one or another subclasses reflecting an intersection of lexical specification and verbal semantics.

Muskogean verbs may have a large number of both prefixes and suffixes. The prefixes mark subject, object, dative, and negative agreement; direction, instrument, applicative, reflexive, reciprocal, and location. A Muskogean verb may be followed by a large number of suffixes showing valence, causation, tense, negation, modality, adverbial modification, mood, and evidentiality/illocutionary force. Consider the following Chickasaw and Choctaw examples, which display some of the possibilities for suffixes.

(7) Chickasaw
Ak-tʃi-hiɬa- <ʔ>tʃ-o-ki-tok-aʔni.
1.SG.NEG.-2.SG.PATIENT-dance-
<GLOTTAL.GRADE>CAUSE-NEG-NEG-PAST-EVIDENTIAL
'I must not have made you dance.'

(8) Choctaw
Hatʃik-im-asíɬɬ-ok-ĩʃa-k-akĩli-h -õ,
2.PL.NEG-3.DATIVE-ask-NEG-YET-COMP-EMPH-TENSE-PARTIC.DIFF.SUBJ
hatʃi-ki-yat ithãna-h-o:ki:.
2.PL.DATIVE-father-NOM know.DUR-TENSE-TRUE
'Even when you (pl.) have not yet asked him, your (pl.) father knows.'

Word Order Properties

Muskogean languages are rather consistently head-final languages: verbs are final in the clause, nouns are final in the noun phrase, and the languages have postpositions (though these may be a subtype of relational noun rather than a distinct word class). Consider the following example from Creek:

(9) Creek
Má tʃokó ó:fa-n apíswa-t
that house in-ACC meat-NOM
ó:tʃ-i:-t ô:m-i:-s.
exist-DUR-SAME.SUBJ be:STAT.PERFECT-DUR-INDIC
'There is meat in that house.'

All Muskogean languages have switch-reference morphology, in which the complementizer of an embedded clause indicates whether the subject of the embedded is clause is the same as the subject of the clause containing the embedded clause.

The following Choctaw example (10) shows that same-subject marking is obligatory even in contexts where there is no possible ambiguity. The Koasati example (11) shows a nice mix of same-subject and different-subject markers from a natural discourse.

(10) Choctaw
Ka:h sa-banna-ha:toko:-ʃ,
car 1.SG.PATIENT-want-BECAUSE.SAME.SUBJ
iskali' ittahobli-li-tok.
money save-1.SG.AGENT-PAST
'Because I wanted a car, I saved money.'

Ka:h banna-ha:toko~,
car want-BECAUSE.DIFF.SUBJ
iskali' ittahobli-li-tok.
money save-1.SG.AGENT-PAST
'Because he wanted a car, I saved money.'

(11) Koasati
Já:li mók itʃo:fi-k tʃokkó:li-n
here also uncle-NOM sit:SG-DIFF.SUBJ
kó:si-k tʃokkó:li-n
aunt-NOM sit:SING-DIFF.SUBJ
i<h>l-ok
arrive<CLAUSE.SEQUENCE>-SAME.SUBJ.FOC
ittim-mánka-to- ~.
RECIP.DATIVE-tell-PASTIII-PHRASE.TERMINAL
'Here also his uncle dwelt, and his aunt dwelt, and he came here, and they spoke to each other.'

The Koasati example also shows that in some cases partial identity is enough to trigger same-subject marking. Note that in this example the verb 'arrive' is marked same-subject with respect to 'speak to each other,' though the subject of the first verb is 'he' and the subject of the second verb is 'they' – a group consisting of the subject of 'arrive' plus the previously mentioned uncle and aunt. Different Muskogean languages (and perhaps different speakers of these languages) seem to follow slightly different principles in deciding whether partial-identity of subject is sufficient for use of the same-subject markers.

Conclusion

All the Muskogean languages are endangered; Mississippi Choctaw and Mikasuki appear to be the only languages that are currently being acquired by more than a few children. And even with these languages, there are indications that the percentage of children in the communities who acquire the language is declining.

The past two decades have seen many tribes recognizing the danger of language loss and initiating language preservation efforts. There have also been major strides in the documentation of the Muskogean languages, with the publication of grammars, dictionaries, and text collections. In the coming decades, the effort to document and preserve these languages will continue to be an issue of great urgency.

Muslim/Islamic Language Education in Pakistan and India

T Rahman, Quaid-i-Azam University, Islamabad, Pakistan

© 2006 Elsevier Ltd. All rights reserved.

The Muslims of Pakistan and India live in multilingual societies: India has 387 languages and Pakistan 69, according to the *Ethnologue* (Grimes, 2000). (For major Pakistani Muslims' languages, see **Table 1**.) Thus, while Muslims in Arabic-speaking countries have to learn only classical Arabic through formal schooling, the Muslims of India and Pakistan learn the Arabic script for religious reasons and learn the language of the domains of power for instrumental ones. Language learning, therefore, has always been an important aspect of education in South Asia.

This article is divided into three parts dealing with the teaching of (1) the classical languages; (2) the modern languages; and (3) the indigenous languages of the Muslims of Pakistan and India.

Classical Languages

Persian

Traditionally, a Muslim child was supposed to have his *bismillāh* (beginning with the name of God) at the age of 4 years, 4 months, and 4 days, but usually this happened at 7 years of age. Children were taught Persian, the marker of elitist identity and the language of the domains of power till the 19th century, through the *khaliqbārī* (a rhyming primer giving Hindvī equivalents of Persian words) and the *karīmā* (a rhymed compendium of moral sayings) of Sa'adī. Later, they were taught the Persian classics (see **Table 2**). Letter writing was an important part of education, and several models of composition (*inshās*) were taught.

Persian lost its power when it was replaced by English at the higher level and by the vernacular languages of India at the lower ones between 1835 and 1837. After this period, it became either a specialized interest for scholars or historians or, which was more often the case, an easy option for students. At present, Persian is compulsory in some Islamic seminaries (*madrasās*) both in India and Pakistan, but the students do not learn how to use the language in real-life situations. In secular institutions, Persian is sometimes an option, but its teaching is so deficient that students do not learn the language in any meaningful sense of the term. However, functionaries of the state are taught modern Persian in a fairly efficient manner.

Table 1 Languages of Pakistan

Language	*Percentage of speakers*	*Number of speakers*
Punjabi	44.15	66 225 000
Pashto	15.42	23 130 000
Sindhi	14.10	21 150 000
Siraiki	10.53	15 795 000
Urdu	7.57	11 355 000
Balochi	3.57	5 355 000
Others	4.66	6 990 000

The population is assumed to be 150 million in 2003 as it was 132 352 000 in 1998 and the growth rate is 2.69%. Source: *Census 2001*: Table 2.7.

Table 3 Arabic texts used in the *Madrasās*

The following books have been commonly used in South Asian *madrasās*. Those not in use nowadays are marked with an asterisk. Those in the original *Dars-i Nizāmī* as given by Sufi (1941:73–75) are in bold type.

Ṣarf (morphology)
Abwāb. c. 19th c. *Abwāb al-Ṣarf* by Hāfiz Muḥammad bin Barak Allah Lakhwi (d. 1893).
Bahāī. c. 16th c. *Sarf-i Bahāī* by Muḥammad bin 'Abd al-Ṣamad al-Harīsī, known as Sheikh Bahā' al-Dīn (1546–1621).
***Fusūl*. c. 17th c. *Fusūl-i Akbarī* by 'Alī Akbar Allahādādī (d. 1680).**
Irshād (S). n.d. *Irshād al-Ṣarf* by 'Abd al-Karīm.
***Mirāh. c. 839 Mirāh ul-Arwāh* by Aḥmad bin 'Alī bin Mas 'ūd.**
***Mīzān*. n.d. *Mīzān al-Ṣarf* by an unknown author (Sheikh Sā 'di; Ḥamzā Badāyūnī; Muḥammad ibn Muṣtafā (d. 1505–1506) are named in different sources).**
***Munsha'ib*. n.d. *Munsha'ib* by Ḥamzā Badāyūnī (Sirājuddīn Awadhī is also named in some sources).**
Muqaddamāt. n.d. *Jama'al-Muqaddamāt* [two works on *ṣarf: Amsalāh* and *Sharḥ Amsalāh*. Taught in Shi'ā *madrasās*].
***Panj*. c. 14th c. *Panj Ganj*, probably by Sirāj al-Dīn Usmānī al-Awadhī (d. 1356)**.
***Ṣarf (M)*. c. 14th c. *Ṣarf-i Mīr* by 'Alī ibn Muḥammad Mīr Sayyid al-Sharīf al-Jurjānī (1339–1413).**
***Shāfiyah*. c. 13th c. *al-Shāfiyah* by Jamāl al-Dīn Abi 'Amr 'Uthmān ibn 'Umar ibn al-Ḥājib (1174–1248).**
Ṣīgha. 1859. *'Ilm al-Ṣīgha* by 'Ināyat Aḥmad Kākōōrvī (1812–1863).

Naḥw (syntax)
'Aqīl. c. 14th c. *Sharḥ Ibn-i 'Aqīl* by Bahā' al-Din 'Abd Allāh bin Aḥmad Ibn 'Aqīl (1298–1367).
***Hidāyat*. c. 14th c. *Hidāyat al-Naḥw* by Sirāj al-Dīn al-Awadhī or Ḥayyān al-Andalūsī.**
**Irshād (N)*. c. 15th c. *Al-Irshād fi' l-naḥw* by Qāzī Shahāb al-Din al-Ghaznawī ad-Daulatābādī (d. 1455).
***Jāmī*. c. 15th c. *Sharḥ kāfiyāh** (Mullā Jāmī)* ***by* Abu Barkat Nur al-Din 'Abd al-Raḥmān Jāmī (1414–1492).**
***Kāfiyāh*. c. 13th c. *Al Kāfiyāh fī 'l-Naḥw* by ābn-Ḥiib.**
***Mi'at*. c. 11th c. *Mi'at 'Āmil* by 'Abd al-Qāhir al-Jurjānī (d. 1078).**
Miṣbāḥ. c. 13th c. *al-Miṣbāḥ fi 'l-Naḥw* by Abul Fatḥ Nāsir bin al-Sayyid Abī'l-Mukarram ibn 'Alī al-khawārizmi al-Mutarrizī (1143–1209 or 1213)
***Naḥw (M)*. c. 14th c. *Naḥw-i Mīr* by Sharīf al-Jurjānī.**
***Sharḥ*. c. 14th c. *Sharḥ Mi'at Āmil* by Sharīf al-Jurjāni or others?**

Rhetoric/Poetics
****Miftāḥ*. c. 12th c. *Miftāḥ al-'Ulūm* by Sirāj al-Dīn Abū Ya'qūb Yūsuf ibn 'Alī ibn Muḥammad al-Sakkākī (d. 1228).**
***Mukhtaṣar*. 1355. *Mukhtaṣar al-Ma'anī* by Sa'd al-Dīn Mas'ūd Ibn 'Umar al Sa'd al-Taftāzānī (1322–1389).**
***Mutawwal*. 1347. al-Taftāzānī.**
Talkhīṣ c. 13th c. *Talkhīṣ al-Miftāḥ* by Abū 'Abd Allāh Muḥammad bin 'Abd al-Raḥmān Jalāl al-Dīn Muḥammad Qazwīnī (1268–1338).

Literature
**'Ajab* c. 19th c. '*Ajab al-'Ujāb fī mā Yufid al-Kuttāb* by Aḥmad bin Muḥammad al-Shirwānī al-Yamanī (d. 1840).
Hamāsah. c. 9th c. *Dīwān-i Hamāsah* compiled by Abū Tammām Ḥabīb (786–845).
Maqāmāt. c. 12th c. *Maqāmāt al-Ḥarīrī* by Abū Muḥammad al-Qāsim al-Ḥarīrī (1054–1121 or 1122).
Mutanabbī. c. 10th c. *Dīwān al-Mutanabbī* by Abū at-Tayyab Aḥmad Ibn Ḥusayn al-Mutanabbī (915–965).
**Nafḥat al-Yaman*. c. 1820s. by Aḥmad al-Yamanī.
Nafḥat. c. 20th c. *Nafhat ul-'Arab* by Muḥammad 'Aizāz 'Alī (1883–1955).
Nahj al-Balāghah c. 10th c. by 'Alī ibn Abī Tālib (600-661). Compiled by al-Sayyid al-Rādī (970–1015).
Qaṣīdāh. c. 7th c. *Qaṣīdāh al-Burdah* by Sharafuddīn al-Busīrī (1212–1296).
Ṣab'a. c. 7th c. *Ṣab'a Mu'allaqāt* by several pre-Islamic Arab poets narrated by Abul Qāsim Ḥammād bin Ṣabūr bin al-Mubārak al-Rāwiyah (d. 772).

Table 4 Newer textbooks of Arabic

Only the most commonly used textbooks are given below. Otherwise, most Arabic texts have translations and explanations in Urdu.

Textbooks of Arabic of all the Textbook Boards of Pakistan from class VI to XII.

Table 5 Differences in costs in major types of educational institutions (in Pakistani rupees)

Institution	*Average cost per student per year*	*Payer (s)*	*Cost to the state*
Madrassas	5714 (includes board and lodging)	Philanthropists and religious organizations	Rs. 1.55 in 2001–2002; An additional sum of Rs. 28.60 for subsidies on computers, books, etc. in some *madrassas* in 2003–2004.
Urdu-medium schools	2264.5 (tuition only)	State	2264.5
Elitist English-medium schools	96 000 for 'A' level & 36 000 for other levels (tuition only)	Parents	None reported except subsidized land in some cantonments.
Cadet colleges/ public schools	90 061 (tuition and all facilities)	Parents and state (average of 6 cadet colleges and 1 public school)	14 171 (average of 5 cadet colleges only)
Public universities	68 000	Parents and state (parents pay an average of Rs. 13 000 per year)	55 000
Public colleges (provincial)	9572	State and parents (parents pay Rs. 1591 per year on average)	7981
Public colleges (federal)	21 281	Parents pay Rs 2525 for B.A. on average.	18 756

Source: Data obtained from several institutions.

The Iranian embassy, too, has made arrangements to teach modern Persian in the *Khonā-i Farhang* centers in Pakistan. In short, Persian is now a foreign language in India and Pakistan that people acquire for instrumental reasons.

Arabic

The other classical language of Indian Muslims, Arabic was always a religious, liturgical language that Muslims learnt to read as a religious obligation. It came to South Asia with Arab merchants who traded on the Malabar Coast and Sri Lanka before the Arab conquest of Sindh in 711–712 C.E. It was used extensively by religious figures, including the mystics (*sūfīs*), whose letters and other writings in Arabic are extant. Books on Arabic grammar and literature were taught in India in the 11th century C.E. (see Table 3).

Arabic was taught in the *madrasās,* which were attended by educated people, intended for religious teaching (*tadrīs*), issuing religious decrees (*iftāh*), and leading prayers, the judiciary (*qazīs*), and the

Table 6 State of the languages of Pakistan[a]

Language	*Material available*
Aer	
Bagri	
Balochi	Alphabet book, primers, folktales, health books, phrase book, Balochi-Urdu-English dictionary, printed books on Islamic observances, poetry, modern literature, textbooks, etc.
Balti	Ancient records (Devanagari-based script), grammar, parables (Roman), verse, folk songs, etc. (Nastaliq script)
Bateri	
Bhat	
Bhaya	
Bhil Sindhi	Material in Sindhi may be used.
Brahvi	Alphabet book, primers, folktales, health books, phrase book, Brahvi-Urdu-English dictionary, printed books on Islamic observances, poetry, modern literature, textbooks, etc.

Khojki (script, not a language)	Ancient records, *Ginans*, old documents, primers, school textbooks, other books
Khowar	Primers, grammar, dictionary, folktales, poetry, religious books, other popular books
Kohistani (Indus)	
Koli (Tharadari)	
Koli (Kachi)	Alphabet books, folktales, health books, stories for children, primer
Koli (Parkari)	Alphabet book, primer, folktales, health books, bilingual vocabulary: Parkari-English, stories for children
Koli (Wadiyara)	
Kundal Shahi	
Lasi	
Loarki	
Marwari	
Memoni	Primers of Sindhi may be used
Od	
Ormuri	Primer, grammar, word list [Roman], verse, prose, grammar, word list: Ormuri (Pashto script)
Pashto	All kinds of textbooks and books; usable in computer (also used in Afghanistan in some domains of power)
Persian	All kinds of books (usable in computer)
Phalura	
Panjabi	Books on literature; history; textbooks, etc. in Nastālīq script (all kinds of books in the Gurmukhi script in India)

Continued

Table 6 Continued

Language	*Material available*
Sansi	
Shina	Poetry, grammar, word lists, folktales, songs, religious books, etc.
Sindhi	All types of books and in computers
Sindhi Bhil	
Siraiki	Ancient poetry, modern literature, magazines, etc.
Torwali	Lexicographic work using Nastaliq is in progress.
Urdu	All types of books and computers
Vaghri	
Wakhi	Primer, word list, folksongs proverbs, word lists
Waneci	Primer, songs, folktales, word lists: Nastaliq (Pashto variant)
Yidgha

bureaucracy (*munshīs*). The curricula of Arabic grammar and literature was standardized in the *Dars-i Nizāmī* by Mullā Nizām Uddīn of Sihalī (a town near Lucknow) (d. 1748).

During the British period, as secular educational institutions developed, Arabic became more strongly identified with Islamic education and religious identity.

In present-day Pakistan and India, Arabic is strongly associated with the Islamic identity. Its script is learnt in order to read the Qur'ān, but the language itself is not learnt by ordinary Muslims. It is a major subject of studies in the *madrasās,* where canonical texts, explained through commentaries and marginal exegesis in Arabic, are still used. However, these texts, ranging from as far back as the 12th century, are used to provide a symbolic continuity with the past. Arabic is actually taught in the *madrasās* through modern, accessible texts such as are used in secular institutions (see Table 4). The Pakistani state also uses Arabic as a marker of Islamic identity. During Zia ul Haq's military rule (1977–1988), Arabic was emphasized in the educational system. It is still compulsory in the state-controlled government schools at the middle level. These attempts, intended to counteract ethnicity and emphasize the Islamic identity of Pakistan, led to the strengthening of Islamic pressure groups in Pakistan.

The Modern Languages

Urdu

Though Urdu, or rather its earlier form called 'Hindī,' 'Hinduī,' or 'Hindvī,' has been traced back to the 11th century, it is a modern language in its present form. There were simple books on religious and romantic themes in circulation among the common people in the 18th century. Poets taught the language informally to their apprentice pupils. However, it was formally taught first by the British at the Fort William College, where early Urdu prose works and grammar were written. The British also introduced it in some schools from 1826 and widely in the 1840s when they established schools in Uttar Pradesh.

By the 1870s, Urdu became an identity symbol of the elitist (*ashrāf*) Muslims who opposed Hindi in the Devanagari script as its rival. A number of institutions, such as Delhi College (established 1792), made Urdu suitable as a medium of instruction at the higher level by translating works of English into it. There are 'Urdu Universities' in both India and Pakistan that are supposed to teach all subjects through the medium of Urdu but still teach some in English. Urdu is not used in the elitist domains of power in Pakistan where, as in India, English continues to hold sway, as it has since British times.

Urdu is, however, the major language of ordinary state schools in Pakistan except in parts of Sindh. Moreover, it is the language of the media and urban life in Pakistan. In most of India, although it is visible at the upper level of academies and university departments, its script is not taught effectively, except in Kashmir where it is the official language. Muslims regard it as an identity symbol and complain that the market conditions discourage their children from learning its script. However, its spoken form is so close to the spoken Hindi of Indian cities and the entertainment sector (songs, films, dramas, etc.), that it is acquired naturally.

English

English has been the major language of power since British rule in both India and Pakistan. Although none of the major Islamic '*ulemā* opposed its learning,

ordinary Muslims regarded it as a symbol of alien rule and a threat to their religious identity. Thus, most did not study English, although some did as early as 1814. Travelers such as Dean Mahomet (1759–1851) wrote in English after settling down in Britain. Muslim prejudice against English was overcome by the efforts of Abdul Latīf (1828–1893) in Bengal and Sir Syed Ahmad Khan (1817–1898) in North India, including the areas now in Pakistan. These interventions, however, came after T. B. Macaulay's 'Minute' of 1835 had officially established the 'Anglicist' policy of making English the language of higher and elitist education in India.

English is now regarded as the language of prestige and power and can only be acquired fluently in expensive private English-medium schools or cadet colleges (public schools on the lines of elitist English boarding-school institutions). In Pakistan, the latter type of institutions are influenced, generally through boards of governors, by the military and the bureaucracy. They are also subsidized by the state (see Table 5). There are also nonelitist, so-called 'English-medium' schools that charge lower fees than the elitist ones, although still high enough to impose a painful burden on the upper-working-class and lower-middle-class parents who send their children to learn English in them. In short, English serves as a marker of socioeconomic class in Pakistan as well as India. While some of the more conservative Muslims, especially in the traditional *madrasās*, feel that this language undermines or dilutes the Islamic convictions and identity of Muslim children, most regard it as an empowering language and, hence, one that Muslims should acquire.

The Indigenous Languages

As the indigenous languages of most Muslims of India and Pakistan were neither the languages of power nor of wider communication, they were generally not taught formally. However, these languages were maintained for reasons of identity. Both Bengali and Sindhi developed into powerful identity symbols because of their ancient literary traditions and because they were used as the languages of the lower domains of power in the Bengal and Sindh, respectively, during British rule. The other languages of Pakistan – Punjābī, Pashtō, Balōchī, Brahvī, and so on – have also been used as markers of ethnic identity to mobilize a pressure group to force the Federal Centre to distribute goods and services more equitably.

Except for Sindhi, no indigenous language is used in the domains of power, including the educational system, at all levels. Pashto is used as the medium of instruction up to class-5 in some parts of the country and in the *madrasās*. However, since students switch to Urdu in the schools after that level and the examinations of *madrasā* students are held in Urdu, they gain more proficiency in Urdu than Pashto. The major indigenous languages – Sindhī, Pashtō, Balōchi, Brahvī, and Punjābī – are optional in some Pakistani nonelitist state schools and colleges. There are also M.A. degrees in all of them. Though language and ethnic activists demand more teaching and jobs in these languages, students opt for the utilitarian options of acquiring English and Urdu. However, some do study these languages as easy options, just as they study the classical languages.

There are primers and textbooks in all the major indigenous languages. In addition, there are chapbooks on religious and romantic themes. Most Pakistani languages are still unwritten, and even those that are written (see Table 6) have little material suitable for teaching them. In the absence of a policy to teach the minor languages in Pakistan, there is no official support for developing such material.

In India, Kashmiri is the only Muslim language besides Urdu. It is associated with Muslims, although both languages are spoken by people of other religions. The official language of the state of Jammu and Kashmir is Urdu, which is taught through the schooling system. Kashmiri written in the Urdu script is also taught, but either as an optional subject or at the higher level.

To conclude, Muslim language education has been governed by both instrumental reasons and reasons of identity consciousness. The languages of power (Persian, English, Urdu) have been learned because they have been the languages of the domains of power, while the languages of identity (Arabic for Muslim identity; Urdu for Pakistani nationalistic identity; indigenous languages for ethnic identities; and English for modern, educated, upper-class identity) have been learned, or merely acknowledged, for the maintenance, promotion, or assertion of identity.

Myth

P Cobley, London Metropolitan University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Myth is commonly assumed to designate the primal stories shared by members of a society or community. It is often thought to consist of fictional narratives which, at root, reveal the most deep-seated beliefs, attitudes, and desires of a group of people. Typically, for Joseph Campbell,

> myth is the secret opening through which the inexhaustible energies of the cosmos pour into human cultural manifestation. Religions, philosophies, arts, the social forms of primitive and historic man, prime discoveries in science and technology, the very dreams that blister sleep, boil up from the basic, magic ring of myth. (1975: 13)

Importantly, then, myth has a fictional bearing: at the very least, it usually contains semifictional stories. As such, myth is frequently contrasted with 'history' and the real. But it is also possible to compare and contrast myth to the deliberate confections of the 'literary.'

Northrop Frye suggests that the Egyptian tale of the two brothers, in which an elder brother's wife attempts to seduce the younger brother, exemplifies a movement from 'credible' myth to a more 'literary' exposition. After the younger brother has resisted his sister-in-law's advances, he is forced to run away, pursued by his enraged brother; he then prays to Ra for assistance, and the god helpfully places a crocodile-infested lake between him and his brother. Although the earlier part of the story is recognizable as 'true to life,' the magical intervention of Ra imbues

Myth

P Cobley, London Metropolitan University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Myth is commonly assumed to designate the primal stories shared by members of a society or community. It is often thought to consist of fictional narratives which, at root, reveal the most deep-seated beliefs, attitudes, and desires of a group of people. Typically, for Joseph Campbell,

> myth is the secret opening through which the inexhaustible energies of the cosmos pour into human cultural manifestation. Religions, philosophies, arts, the social forms of primitive and historic man, prime discoveries in science and technology, the very dreams that blister sleep, boil up from the basic, magic ring of myth. (1975: 13)

Importantly, then, myth has a fictional bearing: at the very least, it usually contains semifictional stories. As such, myth is frequently contrasted with 'history' and the real. But it is also possible to compare and contrast myth to the deliberate confections of the 'literary.'

Northrop Frye suggests that the Egyptian tale of the two brothers, in which an elder brother's wife attempts to seduce the younger brother, exemplifies a movement from 'credible' myth to a more 'literary' exposition. After the younger brother has resisted his sister-in-law's advances, he is forced to run away, pursued by his enraged brother; he then prays to Ra for assistance, and the god helpfully places a crocodile-infested lake between him and his brother. Although the earlier part of the story is recognizable as 'true to life,' the magical intervention of Ra imbues

the mythical episode with "an abstractly literary quality" (1990: 135). Myth, then, consists of stories that inform cultural memory by relating events that might be credible, but are not necessarily tied to the historical record, and might be highly fictional but are not the result of stylized authorial embellishment. As Vernant argues (2001: x), myth represents a category distinct from history and literature in that it does not arise from fact or personal invention but from transmission and memory. It is a story form that exists independently of any particular storyteller.

This last point is of central importance when considering the etymological basis upon which concepts of myth operate. Myth is derived from the Greek word 'muthos.' 'Muthos' presents an interesting case in the matter of translation because it means 'anything that is spoken' and is hence often taken to mean simply 'speech.' However, 'muthos' refers also to 'story,' which, in the origins of narrative, was always spoken (prior to the invention of writing) and was told by a storyteller who was not necessarily the author. After Aristotle especially, 'muthos' became associated with the kind of binding in narratives that adds up to a 'plot' or, as Ricoeur (1984) would say, 'emplotment.' This is particularly prominent in tragedy, for Aristotle, where fate constantly binds the story events that implicate the tragic hero. Frye is one critic who attempts to negotiate the different meanings of 'muthos' inherent in myth and to answer questions about the relation to history and literature. He suggests that there are two broad approaches to myth. First, one can understand myth as a verbal sequence, where the issue of sequence is already an organizing principle in narrative akin to a 'plot.' He adds: "The verbal culture of a pre-discursive society will consist largely of stories, but among those stories there grows up a specialization in social function that affects some stories more than others" (1982: 32). Thus, certain stories take on special significance and there can then be a *second* approach to myth: a focus on the stories that take on a 'sacred' (as opposed to 'profane') ambience. Depending on the approach, then, there are, for Frye, two types of myth, primary and secondary.

Largely because of its Greek derivation in 'muthos,' we tend to associate myth, both primary and secondary, with a Greek model. This ranges from the kind of myths propounded in the works of Homer (featuring the everyday lives of characters as well as the activities of the gods) to Hesiod's *Theogony* where myth is profoundly cosmological. It is hardly surprising, given myth's grounding in speech, in narrative, and in signs, that primary and secondary myths became an important focus for a linguistically based semiotics. Indeed, semiotics' specific treatments of myth have broadly reproduced the split in 'the mythological' between that which is at the deepest, most profound roots of human consciousness and that which is commonplace and everywhere on the surface. The two approaches in question here have had an important influence on the course of semiotics. They are associated with the anthropologist Claude Lévi-Strauss (b. 1908) and the literary/cultural critic, Roland Barthes (1915–1980).

Crucial to Lévi-Strauss's conception of myth is Saussure's insistence on how the differentiality between linguistic signs gives rise to value *(valeur)*. Rather than carrying intrinsic 'meaning,' Saussure argued that linguistic terms were imbued with an identity that relied totally on their difference to other terms. For Lévi-Strauss, in turn, differentiality characterized a range of anthropological phenomena, particularly in the practices of exchange found in kinship rules, but also elsewhere. This included such binary formulations as the 'raw' and the 'cooked,' one of a number of anthropological oppositions discussed at length by Lévi-Strauss in a Saussurean spirit heavily refracted through the work of Jakobson and Troubetzkoy. Taking the oppositions instanced by phonemes as the smallest possible units participating in the differentiality of language, Lévi-Strauss proceeded to formulate a study of myth. He took it as given that myths were stories that gave sense to the society in which they flourished; but he also sought to analyze myth's very basis in order to reveal that its deep-rooted patterns were responsible for the complex surface patterns of the stories themselves. Moreover, he sought to demonstrate that the uniform 'deep' patterns were able to generate a considerable diversity of 'surface' myths. The analogy of phonemes combining and opposing to produce linguistic signs, in particular, provided the paradigm of myth.

Broadly, then, Lévi-Strauss considered myth's roots to be fairly consistent despite the many shifts of narrative that took place across cultures on the surface. As such, he saw mythic narratives as relying on 'mythemes' – a term that directly echoes 'phonemes,' of course. The conclusions that Lévi-Strauss reached about Saussure – that "language can be analyzed into things which are at the same time similar yet different" (1977: 209) – were coupled with his discovery that "anthropology of the nineteenth and even early twentieth century had been content [rather than form], as was the linguistics of the neo-grammarians . . ." (1987: 139). By concentrating on the 'form' by which phonemes were combined rather than on the strictly semantic orientations of a myth's content, Lévi-Strauss devised a method that enabled him to break down all myths to allow the identification of a basic substrate. The most famous example of this is

his 1955 interpretation of the Oedipus myth in which he treats it "as an orchestra score would be if it were unwittingly considered as a unilinear series" (1977: 213):

> Say, for instance, we were confronted with a sequence of the type: 1, 2, 4, 7, 8, 1, 3, 4, 6, 8, 1, 4, 5, 7, 8, 1, 2, 5, 7, 3, 4, 5, 6, 8 . . . the assignment being to put all the 1's together, all the 2's, the 3's, the result is a chart:

1	2		4			7	8
	2	3	4		6		8
1			4	5		7	8
1	2			5		7	
		3	4	5	6		8

He then goes on to break down the features of the Oedipus myth – for example, 'Oedipus marries his mother, Jocasta' and 'Antigone buries her brother, Polynices, despite prohibition' (1977: 214) – which he re-orders in a similar way. Effectively, Lévi-Strauss comes up with four columns of relations in the myth: (a) over-rating of blood relations; (b) under-rating of blood relations; (c) slaying of monsters; (d) (names for difficulty of balance/standing). These mythemes suggest that the orchestrated myth has at its core a common human concern: anxiety over our origins. Put another way, the myth plays out the drama of humankind's quest to determine whether it has been forged in blood/earth or by human reproduction.

Summing up his view of myth in general, Lévi-Strauss concludes, "The kind of logic in mythical thought is as rigorous as modern science, and . . . the difference lies not in the quality of the intellectual process, but in the nature of things to which it is applied" (1977: 230). Here, Lévi-Strauss has used myth as a touchstone for the common concern of 20th-century anthropology: the investigation of so-called primitive cultures to shed light on our own. The myths circulated in 'primitive' cultures are therefore found to be as logical and consistent as the kind of thought procedures that characterize modern rigor. What myth demonstrates above for Lévi-Strauss, though, is that human thought is programmed by a predetermined set of coordinates: a 'language.'

Where Lévi-Strauss proposes that an analysis of 'mythical thought' can reveal the deep structure of the human mind, Barthes' notion of myth, whilst attempting to be equally revelatory, prefers to stay at the surface level. Nevertheless, he shares with Lévi-Strauss a reliance on fundamentally Saussurean principles (and, it may be added, like Lévi-Strauss, his version of Saussure is refracted through the readings of other linguists). Famously, in *Mythologies* (1957; English translation 1973), Barthes drew together a series of brief articles he had written for magazines in the period 1954 to 1956 to demonstrate different aspects of the myth of French life and society. Central to his formulation of myth was the tracking down in the "decorative display of *what-goes-without-saying*, the ideological abuse which, in my view, is hidden" (1973: 11). From the outset, Barthes insists that "myth is a language" (1973: 11); but he also clarifies myth in terms of the following: it is a collective representation (like other definitions of myth, it is not individual or literary); it involves credibility which is sustained by 'inversion' (the element of the fictional but not the fanciful); it is expressed in all places in the contemporary world (whereas, traditionally, myth was only expressed at certain times and places, such as ceremonies); it is susceptible to semiological analysis (as Lévi-Strauss maintained) (Barthes, 1977a: 165–166).

The most obvious difference between the approach to myth outlined by Lévi-Strauss and Barthes is that the latter's version has an absolute grounding in the everyday. Traditional myths tell of heroes and major identity-founding events; concomitantly, they seem to suggest that there is special material – stock situations and characters – that harbours particular aptitude for mythic status. For Barthes, however, *anything* is susceptible to myth, especially the most everyday of phenomena. As he argues, "nothing can be safe from myth" (1973: 131). It can take almost anything and transform its cultural bearing into a natural one. Like Lévi-Strauss, Barthes believes that myth cannot be fixed as a correspondence between a configuration of signs and a stable meaning. Similarly, too, Barthes sees myth as a process of thought that enables the conceptualization of pressing matters in human existence. Yet, where Lévi-Strauss sees myth as framing the profound and sacred, Barthes sees myth as the medium of ideology and the profane. For Barthes, myth is the domain of stereotypes and other means of fixing limits to representation.

The form that the 'speech' of myth takes for Barthes involves systems of 'denotation' and 'connotation.' As Barthes suggests in his analysis of an advertising photograph (1977b: 36–37), there is a tendency for connotation to be foregrounded in representations. Embodied in connotation will also be an ideological travesty of the truth. Despite the foregrounding of connotation, myth uses 'denotation' (straightforward indicating), at the level of the *language-object*, to 'naturalize' what is expressed: "it is the language which myth gets hold of in order to build its own system" (1973: 115). So, for Barthes, myth is a two-level process. Where Lévi-Strauss conceives of myth in terms of 'surface' structures with a concealed, generating layer beneath, Barthes sees

myth as consisting of a dual system at the surface: popular culture and everyday life are 'mythical' because they are 'spoken' through a naturalization. What is 'hidden' in Barthes' version of myth, and what needs to be revealed by semiology, is the *inversion* of real relations that has taken place to transform an ideological proposition into common sense. In this respect, then, the perspectives of Barthes and Lévi-Strauss are similar because they suggest that myth is a process of thought. However, these perspectives are at considerable odds when it comes to the issue of whether myth is comparable to science: Lévi-Strauss hails the rigor of myth, while Barthes condemns its persistence.

Mythologies in Pop Culture

P Cobley, London Metropolitan University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The notion of a 'mythology' as developed by Roland Barthes (1915–1980) is based on an apparently substantial linguistic foundation. For Barthes, a mythology is a phenomenon of everyday life that represents a departure from that which is defined, traditionally, by the term 'myth.' In *Mythologies* (1957; English translation, 1973), Barthes drew together a series of brief articles he had written for French magazines during the period 1954 to 1956. These were his investigations into the nature of contemporary French life, each one a separate 'mythology.' Barthes' aim in drawing attention to these facets of everyday (French) existence was "to track down, in the decorative display of *what-goes-without-saying*, the ideological abuse which, in my view, is hidden" (1973a: 11). The mythologies he singles out in this way, then, include wrestling, the haircuts of the Roman characters in Mankiewicz's film of *Julius Caesar*, the face of Garbo, *steack frites*, striptease, the New Citroën, and the brain of Einstein. Importantly, though, Barthes does not simply expose the power interests underpinning these commonplaces and commodities of everyday life. In addition, he insists that their existence as myths is dependent on the fact that "myth is a language" (1973a: 11). The magazine essays were therefore supplemented by an essay called 'Myth today' in which "semiological analysis [was] initiated, at least as far as I am concerned" (1973b: 9).

Fourteen years after the publication of *Mythologies* in France, Barthes summed up the project of his book as a set of theoretical articulations:

1. Myth, close to what Durkheimian sociology calls a 'collective representation,' can be read in the anonymous utterances of the press, advertising, mass consumer goods; it is something socially determined, a reflection.
2. This reflection, however, in accordance with a famous image used by Marx, is *inverted*: myth consists in overturning culture into nature or, at least, the social, the cultural, the ideological, the historical into the 'natural.' What is nothing but a product of class division and its moral, cultural, and aesthetic consequences is presented (stated) as being a 'matter of course'; under the effect of mythical inversion, the quite contingent foundations of the utterance become Common Sense, Right Reason, the Norm, General Opinion, in

myth as consisting of a dual system at the surface: popular culture and everyday life are 'mythical' because they are 'spoken' through a naturalization. What is 'hidden' in Barthes' version of myth, and what needs to be revealed by semiology, is the *inversion* of real relations that has taken place to transform an ideological proposition into common sense. In this respect, then, the perspectives of Barthes and Lévi-Strauss are similar because they suggest that myth is a process of thought. However, these perspectives are at considerable odds when it comes to the issue of whether myth is comparable to science: Lévi-Strauss hails the rigor of myth, while Barthes condemns its persistence.

Mythologies in Pop Culture

P Cobley, London Metropolitan University, London, UK

The notion of a 'mythology' as developed by Roland Barthes (1915–1980) is based on an apparently substantial linguistic foundation. For Barthes, a mythology is a phenomenon of everyday life that represents a departure from that which is defined, traditionally, by the term 'myth.' In *Mythologies* (1957; English translation, 1973), Barthes drew together a series of brief articles he had written for French magazines during the period 1954 to 1956. These were his investigations into the nature of contemporary French life, each one a separate 'mythology.' Barthes' aim in drawing attention to these facets of everyday (French) existence was "to track down, in the decorative display of *what-goes-without-saying*, the ideological abuse which, in my view, is hidden" (1973a: 11). The mythologies he singles out in this way, then, include wrestling, the haircuts of the Roman characters in Mankiewicz's film of *Julius Caesar*, the face of Garbo, *steack frites*, striptease, the New Citroën, and the brain of Einstein. Importantly, though, Barthes does not simply expose the power interests underpinning these commonplaces and commodities of everyday life. In addition, he insists that their existence as myths is dependent on the fact that "myth is a language" (1973a: 11). The magazine essays were therefore supplemented by an essay called 'Myth today' in which "semiological analysis [was] initiated, at least as far as I am concerned" (1973b: 9).

Fourteen years after the publication of *Mythologies* in France, Barthes summed up the project of his book as a set of theoretical articulations:

1. Myth, close to what Durkheimian sociology calls a 'collective representation,' can be read in the anonymous utterances of the press, advertising, mass consumer goods; it is something socially determined, a reflection.
2. This reflection, however, in accordance with a famous image used by Marx, is *inverted*: myth consists in overturning culture into nature or, at least, the social, the cultural, the ideological, the historical into the 'natural.' What is nothing but a product of class division and its moral, cultural, and aesthetic consequences is presented (stated) as being a 'matter of course'; under the effect of mythical inversion, the quite contingent foundations of the utterance become Common Sense, Right Reason, the Norm, General Opinion, in

short, the *doxa* (which is the secular figure of the Origin).

3. Contemporary myth is discontinuous. It is no longer expressed in long fixed narratives but only in 'discourse'; at most, it is a *phraseology*, a corpus of phrases (of stereotypes); myth disappears, but leaving – so much more the insidious – the *mythical*.
4. As a type of speech (which was after all the meaning of *muthos*), contemporary myth falls within the province of a semiology; the latter enables the mythical inversion to be righted by breaking up the message into two semantic systems: a connoted system whose signified is ideological (and thus 'straight,' 'non-inverted,' or, to be clearer – and accepting a moral language – *cynical*) and a denoted system (the apparent literalness of the image, object, sentence) whose function is to naturalize the class proposition by lending the guarantee of the most 'innocent' of natures, that of language – millennial, maternal, scholastic, etc., (1977a: 165–166).

Concerning point (1), Barthes transforms the customary understanding of myth, and it is a momentous shift toward recognition of the importance of popular culture and the quotidian. Myth is usually contrasted with 'history' (usually a matter of fact tied to the historical record) and the 'literary' (frequently a deliberate fictional confection). Myth is different from both in that it arises "neither from personal invention but rather from transmission and memory" (Vernant, 2001: x); it is a (story) form that exists independently of any particular storyteller and relays not fact or fancy but 'cultural memory.' The continuities with Barthes' notion of myth, then, are evident. The main difference in the latter, however, is the absolute grounding in the everyday. Traditional myths tell of heroes and major identity-founding events; concomitantly, they seem to suggest that there is special material – stock situations and characters – that harbours particular aptitude for mythic status. For Barthes, however, *anything* is susceptible to myth, especially the most everyday of phenomena. As he argues, "nothing can be safe from myth" (1973a: 131). It can take almost anything and transform its cultural bearing into a natural one.

Thus, the work of myth on nearly all cultural phenomena is the work of *inversion*, as Barthes insists in point (2). What the process of myth carries out (in producing a mythology) is a way of uttering a message. To paraphrase Barthes, a football game is a football game, but when it features David Beckham in a leading role, it can become a myth invoking all the platitudes associated with this contemporary cultural icon. The cohesion of such utterances is largely what enables them to become, convincingly, the norm or common sense. The spectacle of wrestling, an example that opens *Mythologies*, has at its core the moral concept that the villain (or 'bastard') will pay for his deeds. It is a formulation of justice in mythic guise, deliberately oblivious, of course, to the fact that individuals evade justice every minute of every day.

Wrestling, then, is a particularly good example of Barthes' third point. That is, that myth cannot be fixed as a correspondence between a configuration of signs and a stable meaning. Rather, it is a discourse or, put another way, it is the framework that makes it possible to remark on and think about various cultural phenomena. Stereotypes are a central part of myth as a discourse because they fix the limits of representation: what does and does not fit a cultural phenomenon. In the history of the representations of African Americans, from the end of the Civil War through the first half of the 20th century, the myth of the 'mulatto' was always bound to stereotypical tragedy because of the mulatto's abortive attempts to 'pass' as 'white.' In this period, a representation of a mulatto without the tragic element would likely be a contravention of the norm and common sense. As Barthes argues, this kind of representation can be *seen* to be *mythical* given the right conditions of analysis, but as long as such recognition is not in place, the representation insidiously sets the boundaries for conceiving what is represented.

Crucially, myth is a type of speech [point (4)]. Like speech, myth produces two levels of signification. Both levels make up a system that Barthes was to elaborate in *Elements of semiology* (1967) five years after *Mythologies,* demonstrating a clear debt to the work of Louis Hjelmslev (see Hjelmslev, 1969). The first level of this system Barthes calls the *language-object*: "it is the language which myth gets hold of in order to build its own system" (1973a: 115). This level is the domain of the signifier (*signifiant*, sound pattern) and signified (*signifie*, mental concept), which Saussure envisaged as being connected in the brain to produce a (linguistic) sign. This is the level at which straightforward indicating takes place: denotation. The second level Barthes dubs *metalanguage*, because it is a language that speaks about the first level. This level is constituted by connotation, and Barthes suggests that it is *cynical* because it is ideological, through and through. It puts forth a proposition (for example, mulatto = tragic) without any conscience. However, it relies on the level of denotation to naturalize the proposition.

Interestingly, Barthes argues in the space of a sentence that it is because of this dominance of the

two-level schema (language/metalanguage) in myth that semiology is licensed to treat writing and pictures in the same way: their signs both partake of denotation/connotation. Thus, in his often quoted essay on 'The rhetoric of the image,' Barthes suggests that the pictorial advertisement for Panzani food products, as with all photographs, foregrounds its connotation overwhelmingly and from the outset of viewing (1977b: 36–37). As such, denotation – a system devoted to establishing the literalness of the object – executes the key part of ideological work for connotation, saying 'this is how it is.' Denotation, then, might vitiate the more fanciful conceptual leaps of connotation by placing the object and anchoring the myth system in a language that appears to be dominated by mere indication. Semiology's task, according to Barthes, is to recognize the operations of these systems and to reveal the invertion that has taken place in the process of a mythology being uttered.

Given the focus of Barthes' concept of 'myth' on popular culture, it was hardly surprising that his work was taken up with great fervor, especially by Anglophone media and cultural studies from the 1970s to the 1990s. The example that Barthes uses in 'Myth today,' that of a photograph on the cover of *Paris-Match* of a black Algerian soldier saluting the French flag, has served numerous commentators as a prime example of the pervasive nature of myth, from Coward and Ellis (1977: 27–29) to Deacon *et al.* (1999: 144–145). Weedon *et al.* deal with Barthes' version of myth better than most. They write:

> Barthes' principal aim in *Mythologies* was to provide a basis for a critique of the 'naturalizing effect' of ideology, its quality of *vraisemblance*. For example, even though she or he may be critical of its connotations, the reader of *Paris-Match* nevertheless believes its denoted 'truth': this event took place, it has a real history and so, in a sense, the soldier's behaviour is 'only natural'. Barthes locates this 'very principle of myth' in the relations between his two orders of signification. The denoted signified establishes the reality of the ideology; it allows myth to be innocently consumed (1980: 180).

However, some media studies versions of *Mythologies* are not so clear. There is a tendency to assume that denotation and connotation exist in a linear, mechanistic relation whereby connotations are conspiratorial supplements working upon simple denotations. Bignell attempts to explain myth with the following:

> It is as if myth were a special form of language which takes up an existing sign system and makes a new sign system out of it. As we shall see, myth is not an innocent language, but one that picks up existing signs and their connotations, and orders them purposefully to play a social role (1997: 16–17).

He adds, "A set of iconic signs which already possess a meaning ('a black soldier is giving the French salute') becomes the basis for the imposition of an important social message, that French imperial rule is fair and egalitarian" (1997: 23). Putting the cart before the horse in this way is characteristic of a great deal of the writing on mythologies in Anglophone media studies (cf. Fiske, 1990: 85–91, and, to a slightly lesser extent, Dyer, 1982: 128).

Ironically, years before Barthes' initial conception of myth was being taken up by cultural critics and media theorists in Britain and North America, he had already shifted the emphasis of his analysis. In his 1971 retrospective on *Mythologies*, Barthes argued that the identification and uncovering of myths were no longer sufficient in the post-1968 world. Myths had become easily recognizable and their exposure a routine exercise. Barthes therefore recommended that work should proceed on the identification of 'sociolects.' The task of semiology was

> No longer simply to *upend* (or *right*) the mythical message, to stand it back on its feet, with denotation at the bottom and connotation at the top, nature on the surface and class interest deep down, but rather to change the object itself, to produce a new object, point of departure for a new science . . . (1977a: 169).

For Barthes, "denunciation, demystification (demythification)" (1977a: 166) of the bourgeois and the petit-bourgeois has become, itself, a mythological *doxa*. 'Mythoclasm' was succeeded by 'semioclasm,' he claimed, and what was needed was a far-reaching interrogation of *all* sign systems and a *challenge* to their very basis. This would not simply entail unraveling the connection of denotation and connotation but a more thorough assault on the mechanics of meaning. For many, this is the very crux of contemporary semiotics.

The Tongue of God

A mythic riddle is solved when God creates the other side of a metaphor, one that owes its existence to the Word, which establishes the prismatically mirrored image of God in man. Now, tenor and vehicle in place, a world comes into being. Lucian tells of the Celtic Ogmios and the Roman Hercules depicted as gods followed by men; the men are attached to God by gold chains, linking their ears to the tongue of God.

Among the Burun and Meban people of Sudan, Juon, the creator, modeled humans out of clay. He knew that man must eat, so he gave him a mouth. Man must be able to dance, to speak, to sing, so he gave him a tongue. God knew that man must be able to hear the sound of the dance, the speeches of great men, so he gave him two ears. God sent into the world a perfect man. In the creation myth of the Dyaks of Sakarra from British Borneo, Salampandai, the creator of humans, fashioned a man of stone and a man of iron, but those men did not speak; when he created a man of clay, the man spoke, and he became the ancestor of all humans.

Some creator gods, such as Awonawilona of the Zuni Indians of New Mexico, are alone at the beginning of time. Then God conceives in himself a thought, and the thought takes shape, just as Awonawilona himself changes into the sun. The thought or the word of the creator god becomes an externalization of the creator, so that the world that results is in fact the shadow of god. Thought, according to the mystics of Islam, is a manifestation of God and the life of the spirit of the universe. Its basis is man. Every path that a human takes leads back to God. A man is a copy of the perfection of God, who is simultaneously creation and creator. God is both seer and seen; the world a mirror of him. A man's essence is the essence of God.

Amma, the Dogon creator of Burkina Faso and Mali, planted a seed within herself and a man was the result. But because of a flaw, the universe contained within it the possibilities of incompleteness. The egg became two placentas, each containing a set of twins, male and female. One of the males, Ogo, broke out of the placenta and attempted to create his own universe. But he was unable to say the words that would bring such a universe into being. His counterpart, Nommo, was killed by Amma; parts of his body were cast in all directions, bringing a sense of order to the world. Amma brought pieces of Nommo's body together and restored him to life, and Nommo became ruler of the universe. He created four spirits, the ancestors of the Dogon people, and Amma then sent Nommo and the spirits to earth in an ark. Along the way, Nommo uttered the words of Amma, and the sacred words that create were made available to humans.

Among the Kwakiutl of Canada, a man built a house in a remote place and then heard numinous noises. He searched and found the house from which the sounds came: sparks were flying from the roof. He looked through a knot hole and saw the Xwexwe dancing. When a certain word was uttered in the song they were singing, they fell, transforming into red cod, with their tails striking the ground and making the noise the man had heard; the words of the song were foreign to the man. The earth in a California Wappo myth was flooded. When the water disappeared, Coyote told Chicken-hawk that he would create people. He took feathers, placed them in a sweat-house that he had created, and

The Tongue of God

A mythic riddle is solved when God creates the other side of a metaphor, one that owes its existence to the Word, which establishes the prismatically mirrored image of God in man. Now, tenor and vehicle in place, a world comes into being. Lucian tells of the Celtic Ogmios and the Roman Hercules depicted as gods followed by men; the men are attached to God by gold chains, linking their ears to the tongue of God.

Among the Burun and Meban people of Sudan, Juon, the creator, modeled humans out of clay. He knew that man must eat, so he gave him a mouth. Man must be able to dance, to speak, to sing, so he gave him a tongue. God knew that man must be able to hear the sound of the dance, the speeches of great men, so he gave him two ears. God sent into the world a perfect man. In the creation myth of the Dyaks of Sakarra from British Borneo, Salampandai, the creator of humans, fashioned a man of stone and a man of iron, but those men did not speak; when he created a man of clay, the man spoke, and he became the ancestor of all humans.

Some creator gods, such as Awonawilona of the Zuni Indians of New Mexico, are alone at the beginning of time. Then God conceives in himself a thought, and the thought takes shape, just as Awonawilona himself changes into the sun. The thought or the word of the creator god becomes an externalization of the creator, so that the world that results is in fact the shadow of god. Thought, according to the mystics of Islam, is a manifestation of God and the life of the spirit of the universe. Its basis is man. Every path that a human takes leads back to God. A man is a copy of the perfection of God, who is simultaneously creation and creator. God is both seer and seen; the world a mirror of him. A man's essence is the essence of God.

Amma, the Dogon creator of Burkina Faso and Mali, planted a seed within herself and a man was the result. But because of a flaw, the universe contained within it the possibilities of incompleteness. The egg became two placentas, each containing a set of twins, male and female. One of the males, Ogo, broke out of the placenta and attempted to create his own universe. But he was unable to say the words that would bring such a universe into being. His counterpart, Nommo, was killed by Amma; parts of his body were cast in all directions, bringing a sense of order to the world. Amma brought pieces of Nommo's body together and restored him to life, and Nommo became ruler of the universe. He created four spirits, the ancestors of the Dogon people, and Amma then sent Nommo and the spirits to earth in an ark. Along the way, Nommo uttered the words of Amma, and the sacred words that create were made available to humans.

Among the Kwakiutl of Canada, a man built a house in a remote place and then heard numinous noises. He searched and found the house from which the sounds came: sparks were flying from the roof. He looked through a knot hole and saw the Xwexwe dancing. When a certain word was uttered in the song they were singing, they fell, transforming into red cod, with their tails striking the ground and making the noise the man had heard; the words of the song were foreign to the man. The earth in a California Wappo myth was flooded. When the water disappeared, Coyote told Chicken-hawk that he would create people. He took feathers, placed them in a sweat-house that he had created, and

transformed the feathers into people. But the people did not speak. Coyote went to Moon to ask for words. Moon put words into a sack, and Coyote went back to the sweat-house and untied the sack, and the people were able to speak.

The World and the Word

A Xhosa storyteller identified the myth-maker's materials: "the world and the word." The Word orders the metaphor, bringing the world into being. Hindu mythology tells of Projapati, hatched from a primal egg; the first sound that he made, the Word, became the earth. The next sound became the sky, and so with the Word, the world came into being. In Egyptian mythology, Ptah the creator was both mind and tongue of the gods, the mind bringing to fruition every creation, the tongue repeating the thought of the mind. In a hymn to Aten, it is said that men's tongues were loosened that they may speak. In an Egyptian gnostic creation myth, God spoke and everything was set into motion. The primal world was under the control of the powerful Word in a Wapangwa myth from Tanzania: it was the disembodied Word that created. The Yuki Indians of northern California tell of the mythic Taiko-mol, Solitary Walker, who created the world from chaos, attempting various linear organizations of the world; then, the plan complete, he spoke the Word, and earth came into existence. Io, or Iho, was the creator of the Maori: Io transformed darkness and water into night and day by means of the Word. Among the Maidu Indians of California, when Earth-Initiate called the stars by name, they came into being. In the Babylonian creation epic, the *Enuma elish*, Tiamat tells Kingu that his Word will dim the fire, humble the weapon. The gods tell Marduk, after he has killed Tiamat, of the power of the Word: open his mouth, and the cloth will vanish; speak again, and the cloth will return.

In the Mayan *Popol Vu*, the creator, Tepeu, and Gucumatz, the maker, said the word, and the earth appeared. So they created light, mountains, rivers, birds, and animals, telling the birds and animals to speak; humans were created by an incantation. Among the Netsilik in Greenland, the first people uttered magic words and could thereby move houses.

The Gospel according to St. John opens, "In the beginning was the Word, and the Word was with God, and the Word was God. . . . And the Word was made flesh, and dwelt among us. . . ." In Genesis, ". . .God said, Let there be light: and there was light." The apostle John wrote in Revelation, ". . .I heard a great voice out of heaven. . . ." In Zoroastrian belief, it was the union of Word and Nature that resulted in the transformation of chaos. Among the Orinoco of South America, the Kahuhana who resided in the Sky Place taught humans how to establish and maintain rhythm with the *wasaha*, the dance stick: when the earth is beaten with the dance stick, and when the words of the Kahuhana song are precisely uttered, the food spirits will be summoned.

Q!aneqelak of the Kwakiutl of Canada heard the voices of many men. He discovered that the voices came from a single man whose body contained many mouths. Q!aneqelak touched the man's body, and all the mouths but one closed. In a Nias creation myth from Sumatra, Luo Zaho created a man, called him Sihai, and then moved him to earth where he died. Out of his mouth grew two trees, from which diseases arose, and from his throat grew a tree from which gold came, and from his heart grew a tree from which humans descended. The sun came out of his right eye and the moon from his left.

Earthmaker, in a myth of the Winnebago Indians of Wisconsin, took a piece of earth and shaped it to resemble himself. But when he spoke to this new being, it did not answer. He made it a tongue; still, it did not respond. He made it a soul; though it did utter something, it was unintelligible. Earthmaker breathed into its mouth, and then the man spoke. In a Siberian-Altaic myth, the word of God gave shape to the world. "Day unto day," wrote the Psalmist, "uttereth speech, and night under night sheweth knowledge. / There is no speech nor language, where their voice is not heard. / Their line is gone out through all the earth, and their words to the end of the world." Gendered order of speech may be significant: in a Japanese myth, because the creator goddess, Izanami, spoke first as she and her creator husband, Izanagi, ritually moved about a sacred column as a part of their sexual ritual, the children whom they conceived were first a monster, then an island. Only when Izanagi spoke first did they produce gods as children.

Gods were masters at the manipulation of the word. In a Kumulipo myth of Hawaii, an early chief, Lono-i-ka-makahiki, cultivated the art of word play and was an expert riddler. And Maui-tikitiki, a trickster god, a shape-shifter, became a master of the double-intentioned word. Gods controlled the means of verbal expression in written as well as oral forms. In a Hopi myth, Hurúing Wuhti, deity of the west, and Hurúing Wuhti, deity of the east, taught the birds and animals created by Hurúing Wuhti of the west to make appropriate sounds. Then Hurúing Wuhti of the east created a man and a woman out of clay. Hurúing Wuhti of the east made two tablets, drew on them with a wooden stick, and gave them to the humans. But the humans did not know what they meant. So the two gods taught the humans

a language. Then they sent them to a place to live. But the gods decided that their creations were not yet complete. Spider Woman, Kóhkang Wuhti, anticipated their wishes and molded a man and woman from clay, sang over them, brought them to life, and taught them the Spanish language. Spider Woman continued to create people, always a man and a woman, giving a different language to each pair. Chinese calligraphy had its mythic beginnings in the marks made when birds hop across sand, in twigs, in marks on the coat of a divine horse. Ts'ang Chien, with four eyes, patterned Chinese characters after nature: the stars he saw above him, the marks on the back of the turtle running, the footprints left by birds on the ground. And Brahma, when he sought a way to write down his teachings, is said to have invented Hindu letters by copying the patterns of the seams of the human skull. In Irish myth, Oghma, created writing, *ogham*, with strokes and notches carved into wood or stone.

The Serpent and the Word

All the animals could talk in a Yuchi myth from Georgia and Oklahoma, and they spoke one language. They were at peace, set free from humans.

In some myths, animals and humans speak to one another. Among the Apache Indians of Arizona and New Mexico, First Man lived with animals; they spoke the same language. Myths of the Cheyenne of the North American plains tell of the paradise created by the Great Power, a paradise where people and animals understood one another. But when a great flood came, humans and animals had to move out of the paradise, and they no longer spoke to one another. An Eskimo myth tells of how, in primal time, humans and animals lived together and were able to transform when they wished, all speaking the same language. Words were magic: when a word was spoken, what it expressed would happen. Nanabozho, the divine trickster of the Chippewa Indians of Canada, was able to talk to all humans and animals. After a devastating flood, he recovered the land along with all living beings, including the Chippewa. Until this time, animals were able to speak, but Nanabozho deprived them of this ability because of their conspiratorial acts against humans.

Sigurdr, in *The Prose Edda* of Snorri Sturlson, killed the villainous Fáfnir; when he was roasting Fáfnir's heart, blood ran onto Sigurdr's finger, and he put his finger to his mouth. As soon as he tasted the blood, "straightway he knew the speech of birds," which then warned him of those who were his enemies. Democritus observed that, because serpents were made of the blood of birds, whoever ate a serpent would understand the language of birds. Arabs and the Paraka of India received premonitions from birds because of their knowledge of birds' language, a knowledge achieved by eating the heart or liver of a serpent. The Viking Rollo understood the language of animals after eating a black serpent. In Scandinavian and German myths, the person who ate the flesh of a serpent would understand the language of animals. In ancient Greece, wise men understood the language of birds after saving the lives of serpents.

Lord Siva, the Sun God, controls human destiny among the Kadar people of India. A poor Kada farmer was told that messengers of death had an appointment with him at his home that night. The cows went to the farmer's home, gave the messengers fine food and milk, and then asked them to be kind to the farmer. As a result, the messengers stole another soul, put it into their bag, and took that to Lord Siva. When Siva learned the truth, he was angry at the cows and took away from them the power of speech.

Reaching to Heaven

"*Ubani ongaphoth' igoda lokukhuphuka aye ezulwini*?" is a Zulu proverb: "'Who can plait a rope for ascending that he may go to heaven?"

In many myths, when humans were created, all spoke one language. A World Tree, or Knowledge Tree, or a tower of some sort became the center of an epical language change, as one tongue gave way to many, and human groups could no longer speak one to the other. In an Armenian myth, three proud men built a tower that was blown over by the wind; at the same time a confusion of languages descended on humans, with the consequence of confoundment and war. The Kabah is the navel of the earth in Malay Charmbook mythology, its branches moving to the corners of the world. Hindu myth tells of a World Tree or Knowledge Tree that grew in the center of the earth, so tall it almost reached heaven. The Tree was proud, determined that its head would touch heaven, its branches would spread over the earth, and all humans would live in its shade, keeping them together as one. Brahma punished the Tree, cutting off its branches and throwing them to the earth where they became smaller trees; with this act, belief, speech, and customs became diverse, and humans were dispersed across the earth. In Scandinavian myth, Yggdrasill, the Mundane Tree, is situated in the center of the earth, its branches covering the earth's surface, its top reaching to heaven. This cosmic tree, the World Tree, was filled with many worlds, its roots moving to the underworld. Three wells were at its base, one of which gave wisdom.

The god Odin gave one of his eyes for a drink from this well; he thence became the wisest of the gods, moving from the oral word to the printed, runic word, which he devised. The Knowledge or World Tree in myth has many manifestations, including the tree of the knowledge of good and evil in Hebrew myth, the tree of life that stood in the middle of Eden and tempted Adam and Eve, leading to their expulsion from paradise.

The World Tree sometimes took the form of a tower reaching from earth to heaven, a means whereby humans might gain access to God. In a number of world myth systems, the Tower of Babel played a significant role in language dispersion. This tower was constructed in Babylon after the great flood. For whatever reason, some say because of the pride of the Babylonians, they decided to build a city and a tower "whose top may reach unto heaven," fearing that they would "be scattered abroad upon the face of the whole earth." When God came down to see the city and tower, he observed, "Behold, the people are one, and they have all one language." He was concerned: "...now nothing will be restrained from them, which they have imagined to do." He therefore decided to "confound their language, that they may not understand one another's speech." God did this, at the same time scattering humans "abroad upon the face of all the earth." Esthonian myth calls this "the cooking of languages." There are African and Australian versions of this myth. In ancient Mexico, the building of the tower was supervised by a giant, Xelhua, called "the architect," one of the seven who were saved from the flood. Bricks were made and conveyed to Cholula, where the tower was constructed. When the top of the tower reached the clouds, the gods were angry; they hurled fire at the pyramid. Many of those who were working on the tower were killed, and each family that worked on the tower was given its own language, so the builders could no longer understand one another, and confusion was the result.

A Confusion of Tongues

When Koevasi, the Melanesian snake goddess, was busy providing the people of the Solomons with their basic needs, her speech was garbled and disorganized, and she therefore passed on to each group a different language. The trickster, Little Coyote, of Ansarkoes myth, was responsible for the different languages when he was the assistant of Old Man Coyote. Old Man Coyote taught people to build homes, make weapons, and hunt. Little Coyote suggested that if Old Man gave the people different languages, they would not understand one another and would therefore use their weapons to make war, and the people would become heroic and wealthy in battles. Old Man agreed, and people, speaking different languages, warred on one another. Hurukan was the Guatemalan god of whirlwind and thunder. He created fire and made the earth and animals. When he ordered the animals to worship him and they responded with animal sounds, he became angry. So he created humans out of wood and then maize. But there was not yet a sun, the humans could not see, and this led to their division. Because they lived apart from each other, different languages evolved.

The Yenisei-Ostyaks of northern Siberia told of the flood and how some people and animals were saved when they climbed onto logs floating in the rising waters. A strong wind blew the logs in many directions, scattering the people. After the flood, they began to speak different languages and form diverse groups. The Maidu Earth-Maker shaped the earth at a time when all was water; he created pairs of humans and deposited them in various parts of the world, each with a different language. The Indo-Chinese people, the Chin, tell the story of a father who instructed his sons to catch a rat. During the chase, the sons got so excited that a multitude of tongues resulted, and they could never again understand one another. In the Voltanic empire of Yucatan was a myth about Voltan, the first man God sent to what is now America. His task was to divide the lands among various peoples who would come after him; he found the ancient ruins of a structure meant to enable people of the past to climb to the sky. Voltan was told that this was the place where God had given to each tribe its own language.

Unombotte, the creator god of the Bassari people of Togo, created a man and a woman and gave them seeds. A tree was the result. Every 7 days, Unombotte came and ate one of the fruits from the tree. When the man and his wife also ate the fruits, Unombotte asked them why they had done this; they said that the serpent had told them they could do so. Unombotte then gave sorghum, yams, and millet to the humans. The numbers of people grew, and they ate in groups, each from its own bowl. From this evolved the differences in language, with each group speaking its own language. Among the Kono of Guinea, Alatangana was the supreme god. Sa, the god of death, while seeking a place to live, created a sea of mud. Alatangana was shocked when he saw this place without light, plants, or living beings. He brought the dirt together and created the earth. Then he created plants and animals, and Sa was pleased. But against Sa's wishes, Alatangana married his daughter; they were parents of 14 children, some black and some white. But they all spoke different languages: this was Sa's

revenge and punishment. In a Kashaya myth, from northern California, Coyote descended into an underground sweat-house where he stuck birds' feathers in a circle, and then said four times, "Let there be people!" Suddenly, the sweat-house was full of people. Coyote gave them separate languages, sending them off to different places.

In the southern part of India, in the Parambikulam area where the Kadar live, is a rock called Maduteenipara. God the Sun summoned all mankind to dinner on that rock. He invited the people to eat beef or buffalo. The Kadar refused both, choosing venison instead. Other groups made their own selections. The Brahmins refused to touch meat at all. Then God separated the different peoples on the basis of their choice of food, instructing them to live in different parts of the world.

Xowalaci, the creator in the mythology of the Joshua Indians of Oregon, shaped a beautiful woman out of tobacco smoke. Because she was lonely, he gave his friend to her. Xowalaci, to bring the man and woman together, made her sleep, and she dreamed that a man was with her but when she awakened there was no man. A child was born, and the woman longed for the father. With the child on her back, she sought him for 10 years. When they got home, she told the child about her dream. She opened the door of her house and saw the man she had dreamed of. Now, the family had many children, and, under the influence of Xowalaci, the children spoke different languages and formed the different tribes.

While his older brother, Kuksu, sang the creation song, Old Man Madumda created the world from a ball of skin from Kuksu's armpit. He made people, but they began to kill each other, so Madumda destroyed them with a flood. Then, from his thoughts, he created a village and people; they too were bad people, so he annihilated them with fire. A third group was created out of willow wands, and when they went bad they were exterminated by ice. Finally, he made out of willow wands many groups, each of which spoke a different language. Then, in this Pomo Indian myth from California, he departed from the world, warning the people to behave properly. Among the Okanagon Indians of Canada is a myth about Old One, who sent Coyote to destroy monsters and to show the Indians how to spread out and live in various places, giving them their names and different languages. In Papua New Guinea in Melanesia, the Papuan Keraki people believe that the first humans emerged from a palm tree. The Great Creator, Gainji, heard voices inside a tree and released the people in separate groups, each of which spoke a unique language. So it was that different languages were spoken in different parts of the world. The Creator of the Snohomish Indians of the Pacific Northwest, as he moved to the west, gave each group of people that he created its own language. He arrived at Puget Sound and liked it so much that he stopped there for a time, with the result that there are many different languages in this area. When it came time to lift the sky (it was so low people kept bumping into it), all humans had to help, but all spoke different languages. They found one word that meant 'Lift together' in all languages, and they were then able to move the sky.

The Broth of Oblivion

The Creator in a Skagit myth gave four names to the earth, insisting that the names would be known to only a few, the argument being that if many people knew those names, the world would change too soon and suddenly. But after a time, everyone came to know the four names, everyone spoke the Skagit language, and when people began to talk to the trees change occurred: there was a flood. Five people escaped the flood in a canoe. A child born to a man and his wife in the canoe became Doquebuth, the new Creator. Old Creator instructed Doquebuth to wave the blanket of the earth and to utter the four names of the earth, and food was provided. Then Doquebuth was told to gather the bones of all those who lived before the flood; the people returned to life. Brains were made for them, and they could talk; they spoke many languages, and Doquebuth blew them to various parts of the world. It was prophesied that a time would come when a new language would be introduced; it would be the only language spoken when the next change came.

In a Chinese myth, Lady Cheng, who lives on the border of hell, prepares the broth of oblivion. Whoever drinks the broth forgets everything and loses the ability to speak. Now, the past erased, the soul is prepared for rebirth.

"A world ends," Archibald MacLeish wrote, "when its metaphor has died."

Nadeljaev, Vladimir Mikhailovich (1912–1985)

O Molchanova, Uniwersystet Szczecinski, Szczecin, Poland

© 2006 Elsevier Ltd. All rights reserved.

Vladimir Mikhajlovič (Mikhailovich) Nadeljaev was born in 1912 in Khabarovsk, and died in 1985 in Novosibirsk. He was a versatile Russian scholar who had an impressive command of a number of Turkic, Mongolian, and Tungusic languages. Under his guidance, 130 higher education specialists were educated in the Tuvan (Tuvin), Altai, Sakha (Yakut), Buryat (Buriat), Mongol (Mongolian), and Kalmyk (Kalmyk-Oirat) languages, as well as experimental phonetics.

It was in East Siberia that he received his primary and secondary education. At the age of 21, he was offered a teaching position at the newly organized school for Dolgan children in Taimyr (a polar peninsular in North Siberia). He accepted the post, and for the first time in his life Nadeljaev encountered a people whose language did not have any records and was passed from one generation to another only orally. Over a span of five years the Dolgan language, which Nadeljaev wrote down and learned, became for him a unique means of survival and access to the traditional lifestyle of reindeer breeders. Nadeljaev retained a lifelong attachment to the Dolgan people. He was further educated at the University of Leningrad (present St. Petersburg), where he studied Mongolian languages under Academician Kozin, experimental phonetics under Academician Ščerba, Professors Zinder and Matusevič, Tungusic languages under Professor Cincius, and Turkic languages under Professor Malov. His years at the university fell during the Leningrad blockade period during World War II. As Nadeljaev was very shortsighted, he could not fight at the front and stayed in Leningrad through the whole year of its blockade: he took part in civil defense, studied, and helped people around him. At that time, he was 176 cm. tall and weighed 48 kg.

In 1958, Nadeljaev became one of the authors and editors of *The old Turkic dictionary* (*drevne-tjurkskij slivar'*), published in 1969. In 1966, Nadeljaev was invited to work at the Siberian Branch of the USSR Academy of Sciences in Novosibirsk, where he founded a new Laboratory of Experimental Phonetics. With the help of laboratory equipment, more than 30 Siberian languages and dialects were tested and researched by laboratory workers and postgraduate students. Nadeljaev worked out the theoretical basis for all investigations at the laboratory. His theory of articulatory bases greatly contributes to the theory of human race and language origin, general phonetics, etc. It holds that the articulatory-acoustic base is a system of articulatory skills that was historically built up at the earliest stages of a particular ethnic group development and is not a language evolution. Considering the articulatory-acoustic base as an ethnological characteristic that might serve as a potential historical source in the reconstruction of ethnic processes, Nadeljaev advanced and justified a series of hypotheses about the ethnogenesis of North Asian peoples. He also put forward a hypothesis about the system of consonants in the Uyghur-Oghuz languages of the Eastern branch of Turkic languages, with a contrast in the degree of tensity: strong vs. weak vs. superweak. A similar system has been retained in several central regions of Mongolia, and this fact became one of the grounds to forward the hypothesis about the Turkic substratum in the Khalkha-Mongolian (Halh Mongolian) language. Scholars also credit Nadeljaev with deciphering a series of messages left in runic script by the Siberian Turkic peoples. Nadeljaev received many honors, including the title of Honored Scientist of the Tuvan Republic, the Medal for Leningrad Defense, and the Badge of Honor.

Na–Dene Languages

J Leer

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, pp. 2665–2666, © 1994, Elsevier Ltd.

The term 'Na–Dene' was coined by Sapir (1915) in the early twentieth century to reify his proposal of a genetic affiliation between the Athabaskan language family and two northwest coast Native American languages: Tlingit and Haida (*see* **Sapir, Edward (1884–1939)** Since then, the nearly extinct Eyak language has been shown to be closely related to Athabaskan, and the inclusion of Haida in Na–Dene has come to be regarded as unprovable by most specialists in the field. The alternative hypothesis is that the similarities between Haida and Athabaskan–Eyak–Tlingit are the result of prolonged areal contact.

Language Classification and Distribution

Athabaskan–Eyak–Tlingit (AET) consists of the Athabaskan language family plus Eyak and Tlingit, contiguous languages of the northern Northwest coast. Athabaskan is located in three main enclaves: northern Athabaskan, Pacific Coast Athabaskan, and Southern Athabaskan. Most researchers agree that the last two are the result of prehistoric migrations southward along opposite flanks of the Rocky Mountains, and that the Pacific Coast migration was earlier than the Southern. Subclassification, especially in Northern Athabaskan, is rendered difficult by the fact that these languages tend to share features with their neighbors, so that it is often difficult to distinguish the inherited from the borrowed.

The Northern Athabaskan languages are spoken in the interior of Alaska and northern Canada. Neighboring the Eskimo of southcoastal Alaska are the Ahtna, Tanaina, and Ingalik; proceeding upriver Holikachuk, Koyukon, Upper Kuskokwim, Tanana, Tanacross, and Upper Tanana are encountered. The latter, together with the Han and Kutchin (or Loucheux), straddle the border between Alaska and Canada. Proceeding southward along the Cordillera, Northern and Southern Tutchone, Tagish, Tahltan, Tsetsaut, Kaska, Sekani–Beaver, Babine, Carrier, and Chilcotin are found. South of the Beaver on the plains live the Sarcee. Continuing in an arc through the Arctic drainage area, are the Chipewyan, Dogrib, and Slavey–Mountain–Bearlake–Hare, whose languages constitute a dialect complex.

Near the mouth of the Columbia River once lived small bands collectively called the Kwalhioqua-Tlatskanai. They appear linguistically closest related to the Pacific Coast Athabaskan of southern Oregon and northern California. Oregon Athabaskan consists of languages spoken in the interior (Upper Umpqua, Galice–Applegate) and a coastal dialect chain (Coquille, Euchre Creek, Tututni, Chasta Costa, Chetco, and Tolowa). The largest California Athabaskan language is Hupa; south of this is Mattole-Bear River and the Sinkyone–Nongatl–Lassik–Wailaki–Kato dialect complex.

The Southern Athabaskan enclave is located in the southwestern United States. The largest and best-known tribe is the Navajo, who reside mainly in Arizona and New Mexico. Most of the Apache languages are geographically and linguistically close to Navajo: Western Apache, Chiricahua–Mescalero, Jicarilla, and Lipan. The most divergent Southern Athabaskan language is Plains Apache (or Kiowa–Apache), spoken in Oklahoma.

Typological Features

The most compelling evidence for AET as a genetic grouping is the profound congruity in the makeup of the verb, as seen in **Table 1** (the lines emphasize major displacements). The AET languages have a 'templatic' structure, such that each element assumes a predetermined position relative to the others. Of particular interest are the 'classifiers,' fused combinations of what were historically separate prefixes: **ł-* (which forms causatives) and **də-* (which forms

passives, reflexives, etc.). An ancient irregularity is the absorption into the classifier of the stative prefix **ŋi-* which combines with **(d)ə-* to yield **(d) i-* in Athabaskan–Eyak and has become a component of the classifier in Tlingit. Verb stem variation also shows ancient similarities, including lengthened stem forms and in Athabaskan and Tlingit, shortening of the stem vowel before consonant suffixes. Haida verb structure exhibits some general similarities with that of AET; for example, the object pronouns precede the subject pronouns.

Other less specific typological traits are also common to Haida and AET; in particular, head-final syntactic structure (postpositions follow nouns; verbs generally come last in the sentence) and the lack or paucity of labial stops and fricatives. However, these traits are shared also with Aleut, a language that is incontrovertibly non-Na–Dene. It has been suggested that these languages, particularly Haida, Eyak, and Aleut, were part of an ancient northern northwest coast language area. If this hypothesis is borne out by archeological evidence, it may put to rest the controversy about the relationship between AET and Haida: Na–Dene will prove to be an areal grouping rather than a genetic one.

Naert, Pierre (1916–1971)

A Pérez Pereiro, Arizona State University, Tempe, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

A major figure in the controversy surrounding the origins of the Ainu language, Pierre Naert was an ardent believer in the inclusion of Ainu into the Indo-European family of languages. Born on May 29, 1916, in Albi in southern France, Naert grew up in the same town as had Jean François de Galaup, Compte de la Pérouse, one of the first European explorers to encounter and describe the Ainu and their language in the late 18th century. Naert studied at the Sorbonne until 1936, when he took a post teaching French in Iceland. Naert's stay there would be short, however, and he moved to Sweden to pursue his studies. He would become a Swedish citizen in 1960.

Naert received his doctorate from the University of Lund in 1946 and became a lecturer and researcher. Although his specialty was Nordic linguistics, Naert broadened his studies to include Basque, Tocharian, and Ainu, among others. He was particularly attracted to threatened and minority languages and demonstrated great concern for the fate of endangered languages and cultures. This eclecticism was cause for concern for many who would have preferred that he focus his research and publishing efforts more narrowly. This concern would become fierce criticism upon Naert's 1958 publication of *La situation linguistique de l'Aïnou*, a book dedicated "to the future of the Ainu people," in which he argued that the Ainu language represents a branch of the Indo–European language family.

The academic community was sharply divided between those who supported his theory, a group that included Louis Hjelmslev and Ivar Lindquist, and those who derided it as nonsense. The Ainu–Indo–European Hypothesis hinged on the supposed relatedness of the Ainu vocabulary to that of ancient Indo-European. The items for study were pulled almost entirely from John Batchelor's Ainu–English–Japanese dictionary, which contains numerous inaccuracies as well as an inconsistent transcription system. In addition, Naert was unfamiliar with both the Ainu and the Japanese languages and did not provide a grammatical description of the language or take into account the influence of Japanese on Ainu.

The controversy took its toll on Naert's career, and he was denied the chair of Nordic languages at the University of Lund. He would eventually take up a position as professor of Nordic languages at the University of Åbo in Finland. His last work on the Ainu was published in 1960. This book, *Aioina: a book on the White people of the Far East*, was an account of his fieldwork in Hokkaido, where he had the opportunity to meet Ainu language informants in person, including Shigeru Kayano, an Ainu speaker and scholar who would later become the first Ainu elected to the Japanese Diet. As the title of the book suggests, Naert had not given up hope that the Ainu would prove to be descendants of ancient Indo–Europeans – a conviction he maintained until his death on June 4, 1971.

Nāgojibhaṭṭa (d. 1755)

S Shukla, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Nāgojibhaṭṭa, also known as Nāgeśa, was a prolific Sanskrit writer. He wrote 93 works ranging from religion and yoga to commentaries on literature and grammar. In the field of grammatical thinking, he is famous for his *Pradīpodyota* ('The Enlightening of That Which Enlightens'), which is a commentary on the *Mahābhāṣyapradīpa* ('That Which Enlightens the Mahābhāṣya') of Kaiyaṭa (12th century A.D.). In many ways Nāgojibhaṭṭa's *Pradīpodyota* is more a commentary on the *Mahābhāṣya* ('The Great Commentary') of Patañjali (2nd century B.C.) than a work that enlightens Kaiyaṭa's *Mahābhāṣyapradīpa*. Nāgojibhaṭṭa's second great work is the *Paribhāṣenduśekhara* ('The High Moon of Paribhāṣās or Interpretive Key-Rules'). *Paribhāṣās* are required for Pāṇini's grammar (5th century B.C.), the *Aṣṭādhyāyī* ('The Eight Chapters'). Most of them are given in his grammar, but there are many that are assumed. The authoritative ones that are not actually given but implicitly assumed in the *Aṣṭādhyāyī* are compiled and commented on by Nāgojibhaṭṭa in his *Paribhāṣenduśekhara*. Equally significant are some of his smaller grammatical works, such as *Vaiyākāraṇa Siddhānta Mañjūṣā* ('The Basket of Settled Conclusions of Grammar') and its shorter version, *Laghumañjūṣā* ('The Small Basket').

The *Paribhāṣenduśekhara* ends with a biographical note (Singh, 1987: 216): . . . *śivabhaṭṭa suta satīgarbhaja nāgēśabhaṭṭa kritaḥ Paribhāṣenduśekharaḥ samāptaḥ*. "Thus ends the *Paribhāṣenduśekhara* written by *Nāgēśabhaṭṭa*, son of Śivabhaṭṭa, born of the womb of Satī."

Nāgojibhaṭṭa was born toward the end of the 17th century in Maharashtra, but for most of his life, he lived and taught in the city of Varanasi, where his genealogical line still continues (Singh, 1987: ii). We know about his date from an incomplete manuscript of his *Bṛhacchabdenduśekhara* ('The great high moon of words') in the collections of the Sarasvati-Bhavan Library, Varanasi. It is dated 1704. Another source for his date is the belief that in 1714 he received an invitation to participate in a religious ceremony by Savai Jayasingh, the ruler of Jayapur, which Nāgojibhaṭṭa declined on the grounds that he had taken a religious vow to never leave Varanasi.

The text of his *Pradīpodyota* was edited by Pandit Shivadatta D. Kudalal and Pandit Raghunath Shastri in 1912. It forms an ancillary text along with Kaiyaṭa's *Pradīpodyota* to the *Mahābhāṣya* of Pātañjali. His *Paribhāṣenduśekhara* was edited and explained by F. Kielhorn in 1868. It consists of 132 *Paribhāṣā*s and their significance and meaning written in simple and clear Sanskrit. For an illustration of his method and style of argumentation, consider the following two *Paribhāṣā*s from his *Paribhāṣenduśekhara* (Kielhorn: 19, 185–86):

Paribhāṣā 38: *pūrva para nityāntaraṇgāpavādānām uttarottaram balīyaḥ*. "Of (these five kinds of rules, for example) a *pūrva* 'prior (rule),' a *para* 'subsequent (rule),' a *nitya* 'perpetual or obligatory (rule),' an *antaraṇga* 'internal (internally conditioned rule),' and an *apavāda* 'exception (rule),' each following (rule) possesses greater force (than any one of, or all of, the rules that are mentioned before it in this *Paribhāṣā*)."

Nāgojibhaṭṭa's comment on the *Paribhāṣā* runs as follows: *pūrvātparam balvat vipratiṣedhaśāstrāt pūrvasya paramm bādhakamiti yāvat*. ('A subsequent (rule) possesses greater force than a preceding (rule); i.e., a subsequent (rule) (as stated in Pāṇini's *sūtra* 1.4.2) supersedes that which precedes it.')

Pāṇini's *sūtra* 1.4.2 referred to by Nāgojibhaṭṭa in his comment is: *vipratiṣedhe param kāryam*. 'When rules of equal force are in conflict, then the last in the order herein given is to take effect.'

Thus, in the formation of the dative plural of *vṛkṣa* 'tree,' from *vṛkṣa + bhyaḥ*, there occurs a conflict between two rules and the question arises as to whether the final *a* of *vṛkṣa* should be lengthened by *sūtra* 7.3.102, which changes *a* to *ā* before a suffix beginning with *bh* (as in the dative singular *vṛkṣa + bhyām > vṛkṣābhyām*), or changed to *e* by *sūtra* 7.3.103, which changes *a* to *e* before a suffix beginning with *bh*. Here the *para* or the subsequent *sūtra* 7.3.103 supersedes, by the present *Paribhāṣā*, the *pūrva* or the prior *sūtra* 7.3.102, and *a* is accordingly changed to *e*. We thus obtain *bṛkṣebhyaḥ*.

Concerning the place of the *apavādas* 'exception (rules)' in the organization of a grammatical text, Nāgojibhaṭṭa cites the following *Paribhāṣā* (62): *pūrvam hyapavādā abhiniviśante paścādutsargāḥ*. ('*Apavādas* or exceptions, it is certain, are considered first (in order to find where they apply); afterwards, the general rules (are made to take effect in all cases in which it has been ascertained that the *apavādas* do not apply).)

Nāgojibhaṭṭa's comment on the *Paribhāṣā* runs as follows: *lakṣṇaikacakṣuṣko hyapavādaviṣayam paryālocya tadviṣayatvābhāvaniścaya utsargeṇa tattallkṣyam sanskaroti* . . . "The meaning is this, that he who is guided solely by the rules (of grammar) first looks

about to find out where the *apavāda* applies, and having thus ascertained that a particular form does not fall under that (*apavāda*), he employs for its formation the general rule . . . ."

The last *Paribhāṣā* cited in the *Paribhāṣenduśekhara* characterizes the traditional belief and the guiding principle that grammatical rules must be expressed with extreme brevity. To secure this brevity, many devices are adopted: cases are used pregnantly, verbs are omitted, leading rules are understood to govern others, and algebraic formulae replace real words. This stated as follows:

Paribhāṣā 132: *ardha mātrā lāghavena putrotsavam manyante vaiyākaraṇāḥ*. 'By saving half a mora grammarians rejoice as much as by having a son.'

The economy and conciseness found in his work attests that Nāgojibhaṭṭa himself practiced the belief expressed in this *Paribhāṣā*. But, as noted by Brough, he was keenly aware of the difference between the realities of language analysis and the actual use of language, as he stated *tad tad arthavibhāgam śāstramātraviṣayam* (*Laghumañjūṣa*: 5) ('The analysis of sounds and the distribution of meanings between stem and affix and between the words in the sentence – these proceedings are the occupation of grammarians.') In other words, in actual usage, the linguistic forms remain as units and convey their sense as units.

Nahuatl

U Canger, University of Copenhagen, Copenhagen, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Nahuatl (Náhuatl) (by some written as Nahua, Nauatl, or Nawat) is also known as Aztec and Mexicano.

Nahuatl forms with Cora and Huichol a branch of the Uto-Aztecan family and is the southernmost language of that family. Today, Nahuatl is spoken in enclaves in 10 Mexican states, from Durango in the west to Tabasco in the east. One variety of Nahuatl, Pipil, by some considered a distinct language, is spoken in El Salvador. Some 10 dialect areas have been recognized; they are different enough that mutual intelligibility is problematic. Of the 500 000 to 600 000 speakers only few are monolinguals, and the language is rapidly losing ground to Spanish.

Speakers of Nahuatl entered Meso-America some 1000 to 1500 years ago from today's northwest Mexico. The best known group, the Aztecs, settled in the Valley of Mexico, where their traditional history goes back to 1300 A.D. It was the renown of their empire that drew the Spaniards to Tenochtitlan, the capital of the Aztec empire and today's Mexico City. As a result and due to the function of Nahuatl as a lingua franca in Meso-America, Nahuatl is the most thoroughly studied and best documented of the languages in the Americas. The earliest known grammar, by Andrés de Olmos, is from 1547; by 1645 another four had been published. Olmos's grammar and Horacio Carochi's from 1645 are exceptionally accurate descriptions of the language. Alonso de Molina's dictionary of Spanish-Nahuatl (about 17 400 entries) and Nahuatl-Spanish (about 23 600 entries) from 1571 has still not been superseded. The Spanish formed the primary target group of the Nahuatl grammars and dictionaries, since they needed to speak Nahuatl in their efforts to educate and evangelize. Faced with the multitude of languages in New Spain, they even argued that Nahuatl should be the official auxiliary language, and in 1570 Philip II declared Nahuatl the official language of New Spain's Indians. As a consequence, Nahuatl was used officially in all contexts; an abundance of letters, complaints, testaments, land deeds, and the like, written in Nahuatl, are found in university libraries in the United States and Europe and in local archives in Mexico, where new ones emerge every year. Nahuatl is thus richly documented over a period of nearly 500 years.

Under the influence of Meso-American languages, Nahuatl has shifted away from some features characteristic of Uto-Aztecan, and the last 500 years of Spanish influence is clearly evidenced. Whereas proto-Uto-Aztecan is reconstructed as verb-final, Nahuatl has verb-first word order, modified-modifier order such as possessed-possessor order, and preposed relational nouns, some of which also function as postpositions. Due to Spanish influence, former relational nouns now function as prepositions. Nahuatl basically is a polysynthetic language with person of subject and object marked on the predicate; incorporation of object and adverbials is widespread, although rare in some dialects, probably due to Spanish influence. The verb is central in Nahuatl both syntactically and in the root corpus; adjectives are derived from verb roots; and derivation is richly developed.

Phonologically, Nahuatl is uncomplicated with four vowels, short and long; 15 consonants, no voiced stops; and currently a fixed stress on the penultimate syllable

Named Entity Extraction

R Grishman, New York University, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Named entity (NE) extraction is the task of identifying and classifying the names in a text. Many types of text contain a significant proportion of names and cannot be properly analyzed unless these names are identified. For example, understanding a news story requires the ability to recognize the names of people, places, and organizations.

NE recognition has received considerable attention since the mid-1990s because it is both practically important and computationally relatively tractable. The task was introduced for English in 1995 as part of Message Understanding Conference 6 (Grishman and Sundheim, 1996). It included three classes of names – people, organizations, and locations – as well as date and time expressions, monetary expressions, and percentages. NE recognition was soon extended to several foreign languages (Spanish, Chinese, and Japanese) in the Multilingual Entity Task (MET) evaluations (Chinchor, 1998) and has since been applied to a large number of languages.

Text annotation for NE is typically done using an XML notation, with a 'type' attribute indicating the type of name. For example,

Press secretary <name type = "person">Ima Rite </name> announced that President <name type="person">Dean</name> would attend the meeting of the <name type = "org">World Trade Organization</name> in <name type="location">Paris</name>.

Texts in different domains have different classes of names, and the NE task has had to be adjusted accordingly. For example, for biomedical texts the principal name classes have included gene and protein names (Collier *et al.*, 2000). Current question-answering technology has come to rely heavily on NE tagging to identify suitable answers. For example, a simple question-answering system may seek to answer *In which city is the Alhambra located?* by looking for names of type 'city' appearing in close proximity to *the Alhambra* in a large text corpus. This use of NEs has led to both finer distinctions and more comprehensive classifications, with some NE systems now including over 100 classes (Sekine and Nobata, 2004).

The first NE recognizers were based on manually constructed regular (finite-state) patterns that reflect the various clues that can be used to classify names. For example, a person name can usually be recognized by being preceded by an honorific (such as *Mr* or *Ms*) or title (such as *President* or *Governor*) or by beginning with a recognizable first name (such as *Adam* or *Alice*). This can be captured by patterns such as:

person-name = titled-person | person-with-known-first-name

titled-person = honorific capitalized-word+ | title capitalized-word+

honorific = 'Mr' | 'Mrs' | 'Miss' | 'Ms' | 'Dr' | . . .

title = 'President' | 'Prime Minister' | 'Governor' | 'Gov.' | . . .

person-with-known-first-name = known-first-name capitalized-word*

known-first-name = 'Adam' | 'Alice' | 'Albert' | . . .

Here, in regular expression notation, we use * to indicate zero or more repetitions of an element, and + to indicate one or more repetitions of an element. By hand-annotating the names in a text corpus and repeatedly comparing recognition performance against this corpus, it is possible to develop an accurate recognizer for the most common name types. However, this is a quite labor-intensive process requiring considerable skill.

Corpus-Trained Taggers

To reduce the skilled labor required, many name recognizers (or name taggers) have been developed that can be automatically trained from annotated corpora. One of the first such corpus-trained models was the Nymble system (Bikel *et al.*, 1999), based on Hidden Markov Models (HMMs). For a name tagger with n name types, an ergodic HMM with $n + 1$ states was constructed – one state for each name type, plus one for the not-a-name (NaN) state (**Figure 1**). To improve the performance of the HMM, transition probabilities in Nymble were conditioned on the prior word, emission probabilities were conditioned on the prior word or state, and several levels of back-off were provided.

Another early approach to corpus-trained name tagging used maximum entropy (ME) models (Borthwick *et al.*, 1998). The ME approach has the benefit of easily allowing the incorporation of specific clues for identifying a particular name type. For example, if a list of common first names is available, the membership of a token in this list can be used as a feature for detecting person names. If a regular expression has been developed for a particular type of name, matching this expression can be treated as a feature within the ME framework.

Figure 1 Markov model for a name recognizer with two name types (person and organization names).

More generally, name tagging can be viewed as a token classification task, so that any type of classifier can be used to construct a name tagger. If the name types are X and Y, we assign the tags B-X and B-Y to the first tokens of names of those types, the tags I-X and I-Y to subsequent tokens of such names, and the tag O to tokens that are not part of a name (this is one of many possible tagging schemes). A large number of trainable classifiers have been applied to the name tagging task (see, e.g., the papers in Daelemans and Osborne, 2003). By annotating a corpus and then training one of these classifiers, it is possible to create a name tagger of moderate quality for a new domain or language in a few weeks (May *et al.*, 2003).

These NE classifiers rely primarily on relatively simple, local features: the identity of the current token, the preceding and following one or two tokens, and capitalization (for languages with capitalized names). A variety of other features have been employed to enhance performance, including presence on word lists (such as lists of common first names or titles), orthographic patterns (for example, presence of a hyphen or ampersand), parts of speech, and affixes (Daelemans and Osborne, 2003). In addition, NE taggers frequently use some form of name cache, which records name tokens previously tagged within the same document. If such a token occurs again later in the document, the tagger will, in the absence of other information, assign the token the same name type. For example, if the name *Fazar Fastener Corp*. appears at the beginning of a document (and is tagged as an organization), a later reference to *Fazar* (by itself) will also be tagged as an organization.

The amount of data that needs to be annotated for a given level of performance can be reduced by as much as 80–85% through the use of active learning (Miller *et al.*, 2004; Shen *et al.*, 2004). Instead of annotating all the names in a corpus sequentially, we can begin by annotating a small portion of the corpus and building an NE model from that. This model is then used to tag the remainder of the corpus and, in particular, to identify tokens or sentences in the corpus about which the model is relatively uncertain. These tokens or sentences are then presented for manual tagging, the model is rebuilt (with the additional manually tagged training data), and the process is repeated.

Lightly Supervised Taggers

Several algorithms have been developed for creating NE taggers from much smaller training samples, typically on the order of a dozen names for each type of name (a seed set). Although the methods differ in detail, they all follow a general bootstrapping approach. Given the seed sets of names, the algorithm begins by looking for all instances of these names in a large (untagged) corpus and collecting the contexts of these name instances. A context that appears around two or more names of type T, and no names of type $T' \neq T$, is a good indicator for type T. We then look at other names (not in the seed set) that appear in these contexts. A name that appears in two or more contexts that are indicators of type T is probably a name of type T. These names are added to the seed sets of the respective types and the process repeats, gradually classifying more and more names.

Specific procedures differ in terms of the types of contexts that are used. Strzalkowski and Wang (1996) used the words immediately preceding and following the candidate names; Collins and Singer (1999) classified words that appeared in specific syntactic contexts. In general, such discovery procedures work much better when multiple word classes are being built concurrently so that positive examples of one class can serve as negative examples of other classes (Lin *et al.*, 2003).

Evaluation

The basic idea for evaluation of NE taggers is straightforward. We select a test corpus, generate an answer key by tagging the corpus manually, and

generate a system response by running the tagger. Any name tag in the response that exactly matches one in the key is 'correct,' one in the response that does not match anything in the key is 'spurious', and one in the key that does not match anything in the response is 'missing'. We then define recall = correct / (correct + missing) and precision = correct / (correct + spurious). The F measure, the geometric mean of recall and precision, is often reported when a single quality measure is required.

The Message Understanding Conference evaluations used a evaluation metric that gave partial credit for certain errors – correctly identifying some tokens as a name but assigning it the wrong name type or correctly identifying the name type but making an error on the extent (start or end point) of the name. The resulting scores, of course, are somewhat higher than with the strict measure.

Typical (strict metric) F measures for a small set (3–5) of name classes range from the low 80s to low 90s, depending on the language, domain, and amount of training data. Some languages are easier to tag than others (in particular, languages in which names are distinguished by capitalization are easier). However, even for the same tagger, language, and set of name classes, performance can vary widely depending on the choice of test corpus. Performance is affected by the overlap of names between the training and test corpora, and this is likely to be greater if the texts are on the same topic and from the same time period. These factors should be kept in mind when the results of different evaluations are compared.

Names and Proverbs: Religious Significance

A Kimenyi, California State University, Sacramento, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

All societies have philosophies and religious beliefs. The content of a philosophy or belief structure becomes very clear when societies have written documents, such as the Bible or the Qur'an, or when holy people in the society preach, explain, and interpret those documents. In oral societies, however, it is not easy to draw the line between philosophy and religion on the one hand, and on the other hand to know for sure what they are, because oral texts are ambiguous and many times contradictory. By examining the language Kinyarwanda (Rwanda), it is possible to show that a society's language can shed light on the worldview and religious beliefs of its people. The lexicon, personal names, proverbs, greeting expressions, swear words, and insults in the countries of Rwanda, the Democratic Republic of Congo, Tanzania, and Uganda, where Kinyarwanda is spoken, as in other regions of the world, provide information about the values of the people who speak the language, about their philosophy, and about what they think about God. The linguistic elements reveal, for instance, how people conceptualize God and conceive his physical and moral attributes, and his relation to the world and to the people.

Concept and Names of God

The name of God in Kinyarwanda is *Imana,* pronounced [imáana] (where ′ indicates high tone). Morphologically, *Imana* consists of three morphemes: the preprefix /i-/, the class marker /-n-/ for class 9 (CL 9) nouns, and the stem /-máana/. The morphological representation is thus /i+n+máana/. Nouns belonging to this class pluralize in class 10. In this instance, the singular and the plural are the same in form. The difference is manifested only in the prefix taken by modifiers of the noun. For demonstratives and possessors, for instance, the prefix is /yi-/ for singular and /zi-/ for plural, as shown by the following expressions: [imáana y'í rwaanda] 'God of Rwanda' and [imáana izo] 'Great! So much the better' (literally 'those gods'). The word *Imana* provides no information, however, about the nature of God – whether God has anthropological features, for example – nor does it indicate information about God's gender. What is certain, as revealed by a regional proverb, is that *Imana* does not have a family, wife/husband, or children:

(1) Imana ntigira umuryango.
God doesn't-have family
'God doesn't have a family.'

This proverb implies that God is impartial and does not take sides or favor some individuals over others. Other names used to refer to *Imana* provide further insight into 'his' attributes:

- *Nyagasani* [nyagasani] /nya+a+ka+sani/ 'the one who has luck.'
- *Rugira* [rugirá] (from the verb *kugira*) 'the one who causes everything' or 'the owner of everything.'
- *Rurema* /ru+rem+a/ (CL11+create+asp) 'the creator.'
- *Iyakare* /iya+kare/ (of+CL9+early) 'that of early' or 'of times immemorial.' (This name implies that God is 'ancient,' or the oldest being.)
- *Iyambere* /iya+imbere/ (of+CL9+before) 'the one of before.' (This name implies that God was the first to exist, preceding everything.)

Physical and Moral Attributes of God

Imana is very much similar to the Christian God. In Kinyarwanda, *Imana* is the creator of everything, is almighty, knows everything, and is everywhere. *Imana* loves his creation, he loves everybody, and does not discriminate. Personal given names, as in Examples (2)–(4), and proverbs, as in Examples (5)–(7), illustrate these attributes:

(2) Niyongabo
It-is-it-that-is-shield/warrior
'It is He who is almighty.'

(3) Niyonzima
It-is-it-that-is-healthy/alive
'It is He who is healthy/alive.'

(4) Niyonkuru
It-is-He-who-is-old/great/important
'It is He who is the oldest/the greatest/the most important.'

(5) Umubande w'ibyago urutwa n'imanga y'Imana.
valley of misery is-inferior to precipice of God
'The valley of misery is inferior to God's precipice.'

(6) Imana ntigira inzigo.
God doesn't-have revenge
'God doesn't avenge/ retaliate.'

(7) Imana ntivuna.
God doesn't-tire/exhaust
'God doesn't create problems (for anybody).'

The proverbs show that Imana is thought of as good and generous and that he does not bear grudges. The expressions given in Examples (8) and (9) show that *Imana* is also thought of as a good and caring parent and guardian:

(8) kurota Imana
to dream God
'Good night'

(9) kubana n'Imana
to live with God
'Bye-bye'

Names Related to God

The many personal names for God in the Kinyarwanda language reveal how the people in the culture conceive of God. Clearly, there is only one God, and he is almighty, the creator of everything, omniscient, good, and generous:

Niyibizi	'It is He who knows'
Niyonsenga	'It is Him that I pray to'
Niyonsaba	'It is Him that I ask for help'
Habarurema	'The creator exists'
Habarugira	'The causer/possessor exists'
Habonimana	'Only God sees'
Habyarimana	'Only God gives birth'
Hakizimana	'Only God cures/saves/makes rich'
Havugimana	'Only God speaks'
Hitimana	'Only God gives names'
Hategekimana	'Only God rules'
Manirakiza	'God saves/cures/makes rich'
Manirareba	'God watches'
Maniragaba	'God gives'
Bizimana	'Only God knows it'
Bimenyimana	'Only God knows/understands it'
Nsengimana	'I pray to God'
Nsengiyumva	'I pray to the one who understands'
Nizeyimana	'I trust God'
Ngendahimana	'I walk because of God/I walk in God's space'
Ndahimana	'I am/exist because of God'
Nahimana	'It is up to God'
Nkunzumuremyi	'I like the creator'
Mbarushimana	'I have God on my side more than you/them'
Mukeshimana	'I have him/her because of God'
Muhawenimana	'S/he given to me by God'

Predestination

The Banyarwanda (speakers of Kinyarwanda) believe that before everybody is born, God has already decided each human being's destiny, and that nothing can be done to change the course of a life. This is illustrated by the following proverbs:

(10) Uhawe n'Imana ntiyamburwa n'umuyaga.
who-is-given by God is-not-dispossessed by wind
'S/he who receives something from God is not dispossessed by the wind.'

(11) Umwanzi agucira icyobo
enemy makes-for-you hole
Imana igucira icyanzu
God makes for you compound-exit
'An enemy digs a hole for you while God is making a secret exit for you.'

(12) Umugisha w'Imana ntuhamagarwa urizana.
blessing of God is-not-called it-comes-by-itself
'God's blessing is not called, for it comes by itself.'

(13) Uwarasiwe n'Imana ni we
is-shot-for by God is him/her
urasirwa n'inshuti.
is-shot-for by friends
'S/he who God has shot the game for, s/he is the one that friends shoot for.'

(14) Uwo Imana ihaye amata ntashyiramo amazi.
whom God gives milk doesn't-put-in-it water
'S/he to whom God gives milk doesn't mix it with water.'

(15) Ntawiha icyo Imana itamuhaye.
nobody-gives-himself/herself what God doesn't-give-him/her
'Nobody can give himself/herself what God has not given him/her.'

(16) Upfuye akuruta n'iyo ageze
who-dies is-superior-to-you even if arrives
ikuzimu arakuruta.
underworld is-superior-to-you
'S/he who dies superior to you, even when s/he arrives in the underworld remains superior to you.'

(17) Wibwira neza ugahirwa nabi.
you-tell-yourself well you-are-lucky bad
'You plan well but you don't succeed well.'

(18) Iyo urupfu rwagutumiye nturara.
when death invites-you you-don't-spend-the-night
'When death invites you, you can't spend the night.'

(19) Nyamunsi ntitsindwa.
destiny is-not-surpassed
'Destiny is never defeated'

(20) Iminsi nticuza Imana.
days don't-dispossess God
'Destiny doesn't dispossess God.'

(21) Iyo nyamunsi yaciye ishumi, nta
when destiny cuts link there-is-not
mubyeyi uyihisha ikibando.
parent who-hides-from-him baby
'When destiny cuts the link, there is no mother who can hide her baby.'

(22) Iyo Serupfu yaje,
when Death comes
Semiti ntaharara
Medicine doesn't-spend-the-night-there
'When Death comes, Medicine doesn't spend the night.'

(23) Hagena Imana.
there-decides God
'It is God that decides (everything).'

(24) Hica umunsi.
there-kills day
'It is destiny that kills.'

(25) Icyo Imana iguhaye urakira.
what God gives-you you-accept
'What God gives you you accept.'

(26) Icyo Imana igututse ni cyo kikwica.
what God insults-you is what kills-you
'God's curse on you is what kills you.'

(27) Icyo umuntu agaya Imana
what person criticizes God
irara ikirema.
spends-the-night creates-it
'What a person criticizes of God, God spends the night creating it.'

(28) Iminsi ikora umugabo mu nnyo ngo shiii.
days touch man in anus it-makes [shiii]
'Destiny mocks people.'

(29) Iminsi irisha umugabo ikivuza.
days make-eat man an-old-squash
'Destiny makes a man eat an old squash.'

Why Rwandans Do Not Pray to God

In Rwanda and many other societies, people become religious and turn to God mostly when they are in trouble, have serious health problems, or are getting very old, thus approaching death. To pray to God in these circumstances is seen in traditional Rwanda as trying to bribe him, which can be too costly. This belief is illustrated by the following proverb:

(30) Imana iraguha, ntimugura,
God gives-you you-don't-buy,
iyo muguze raguhenda.
if you-buy he-overcharges-you
'God gives you, you don't buy from him; if you buy, he overcharges you.'

The Kinyarwanda-speaking people also believe that God does not need their prayers. Since *Imana* is omniscient, omnipotent, good, and generous, he can save people from their trouble when he wants to. He has his own plans and is very patient. He does not act or react on the spot of the moment, as illustrated in examples (31)–(33):

(31) Imana itanga ishaka.
God he-gives he-wants
'God gives when he wants.'

(32) Imana niguha ntuyimanuze.
God if-he-gives-you don't-ask-too-much-from-him
'If God gives you (something), don't ask for more.'

(33) Imana irahora amaherezo igahora.
God keeps-quiet/silent in-the-end he-avenges
'God keeps quiet/silent but in the end he avenges.'

Further, to pray to God is seen as *kugondoza Imana* 'asking too much from God,' as shown by Examples (34) and (35), two proverbs that warn people not to abuse God's generosity. It is believed that prayer is a waste of time, since, knowing everything and caring about his creatures, *Imana* may intervene without being asked.

(34) Ugowe agora Imana.
Who-is-exhausted exhausts God
'Who is exhausted exhausts God.'

(35) Ukanura cyane Imana igafata
You-stare a-lot God touches
mu ryayo.
in his (eye)
'When you stare too much God closes his (eye).'

Rwandans believe that God has done a lot for people and needs to be left alone. The relationship with God is personalized. There are no holy days or holy places for him. There is no need to preach about him, because nobody doubts his existence, and there is no need for proselytizing. Instead of praying to God or worshiping God, Rwandan people pray to or worship *abazimu* 'spirits.' Families have shrines where they go and talk to the spirits of their ancestors. These shrines are called *indaro*, phonetically [indáaro], from /i+n+ráar+o/, meaning 'a place where one sleeps.' The stem /–ráár-/ means to sleep, /i-/ is the preprefix, /-n-/ is the prefix marker for class 9, and /–o/ is the nominalizer suffix.

The Paradox of a Transcendent and Immanent God

Although *Imana* spends the night in Rwanda and cares about everybody, he always appears to be remote and removed. He does not interfere with people's lives and actions. He allows people to do whatever they want, whether it is good or bad. Rwandans thus understand that they have to depend on themselves to improve their lives and to make their world a better place to live. The language of the proverbs shown in Examples (36)–(41) illustrates this belief:

(36) Imana ifasha uwifashije.
God he-helps who-helps-himself/ herself
'God helps those who help themselves.'

(37) Habyarimana abantu bakarera.
there-gives-birth-God people they-raise
'It is God who gives birth and it is the people who raise (the children).'

(38) Imana ikubyarira si yo ikurerera.
God gives-birth-for-you it-is-not him raises-for-you
'The God who gives birth to your children is not the one who raises them for you.'

(39) Imana iguha inka, ntikubwiriza kuziragira.
God gives-you cows doesn't-tell-you to-graze-them
'God gives cows to you but he doesn't tell you how to teach them to graze.'

(40) Haba Rugira haba rugizi.
there-is Causer there-is agent
'There exists the causer and there exists the doer.'

(41) Abagiye inama Imana irabasanga.
those-who-ask-each-other advice God joins-them
'Those who consult each other, God joins them.'

Since Rwandans have to take their destiny into their own hands despite the existence of a caring and loving God, human beings who fail to fulfill their responsibilities to contribute to the society are linguistically demoted from the 'human being' category (marked by the prefixes /-mu-/ and /-ba-/ for the singular and the plural forms, respectively, referred to in Bantu linguistics as class one 1 and class 2) to the 'inanimate objects' category (marked by the prefix /-ki/- of class 7), as shown by the language in the following examples. (Note that /-ki-/ changes into /-gi-/ before nominal stems which start with a voiceless consonant (Dahl's Law).)

[ikiréemba]	'impotent'
[ikimára]	'useless individual'
[ikimúga]	'a person with many health problems'
[ikiréma]	'a crippled person'
[ikiragi]	'a mute person'
[igipfáamatwí]	'deaf person'
[igikuri]	'dwarf'
[igisaambo]	'thief/crook'
[igicúucu]	'stupid'

The philosophy reflected in this vocabulary is very similar to existentialist philosophy because of its activism and humanism.

Conclusion

It is possible to know something of people's religious beliefs through knowledge of their language. The vocabulary of a people contains all of the concepts that are in the collective knowledge of their society. The language of the culture as expressed in onomastics, proverbs, exclamations, and expressions adds further information in a particularly clear way.

Namibia: Language Situation

J U Kavari, University of Namibia, Windhoek, Namibia

© 2006 Elsevier Ltd. All rights reserved.

The territory that is presently known as Namibia was known by the name South West Africa during the colonial period. It is a country on the southwestern side of Africa with a size of 824 269 square kilometers. It borders Angola in the north, Botswana and Zambia in the east, South Africa in the south, and the Atlantic Ocean in the west. It is inhabited by close to 2 million people, of whom the Oshiwambo-speaking Namibians make up the largest ethnic group. Languages in Namibia may be classified into three groups: Bantu, Khoesan (Khoisan), and European languages. The most comprehensive study of the language situation in Namibia to date is by Maho (1998).

Bantu Languages

Bantu languages are characterized by common typological features, such as a balanced symmetrical vowel system, distinctive tone, agglutinating word-formation process that includes a wide variety of derivative affixes, highly grammaticalized noun class systems with a rich concordial agreement system, a highly complex verb conjugation system that includes a rich set of tense-aspect distinctions, and a syntax based on SVO word order (Maho, 1998).

The majority of Namibian languages are Bantu languages, and they are also the largest Namibian languages in terms of numbers of speakers. The Namibian Bantu languages can be divided into the following groups (the number of speakers are based on Grimes, 2000):

- Otjiherero (Herero): 125 000 speakers, including 12 000 speakers of Oludhimba
- Oshiwambo dialects: Oshindonga (Ndonga), Oshikwanyama (Kwanyama), Oshimbalanhu (Mbalanhu), Oshikwambi (Kwambi), Oshingandjera (Ngandjera), Oshikwaluudhi (Kwaluudhi) and Oshimbandja (Mbandja): 713 919 speakers altogether
- Kavango languages: Rukwangali (Kwangali), Thimbukushu (Mbukushu), Rugciriku (Diriku) and Shishambyu (Sambyu): 128 400 speakers altogether
- Caprivi languages: Cisubiya (Subiya), Silozi (Lozi), Shiyeyi (Yeyi), Chifwe (Fwe), Chitotela (Totela), Mbalangwe, and Mashi: 62 300 speakers altogether
- Setswana (Tswana): 6050 speakers in Namibia

Based on these figures, the total number of speakers of Namibian Bantu languages is just over 1 million, but it is likely to be higher as many figures in the list above date from the early 1990s. The language group with the largest number of speakers comprises the Oshiwambo dialects. A number of Namibian Bantu languages are also spoken outside Namibia, in particular those spoken in the north of the country and in the Caprivi; these languages include Silozi (Lozi) in Zambia, Oshikwanyama in Angola, and Otjiherero (Herero) in Angola and Botswana. Setswana is the national language of neighboring Botswana.

All Namibian Bantu languages are tone languages as they make lexical, grammatical, and expressive tonal distinctions.

Khoesan Languages

Namibia is home to a number of Khoesan languages, the smallest African language family. Khoesan languages are only spoken in Southern Africa (except for two languages spoken in Tanzania), and most of them are highly endangered. The only Khoesan language with over 100 000 speakers is Khoekhoegowab (Nama), spoken by 176 201 speakers in Namibia (plus another 5000 in South Africa and between 200 to 1000 in Botswana). All remaining Namibian Khoesan languages have fewer than 30 000 speakers (Grimes, 2000), although some are also spoken in the neighboring countries of Angola and Botswana:

- !Xóõ: 200 speakers in Namibia
- ǂĀkhoe: 5000 speakers in Namibia and Angola
- //Kh'au//'e: 2000 speakers in Namibia
- Hai//om: 16 000 or fewer speakers in Namibia
- Ju/'hoan: 25 000–30 000 speakers, together with !Xun (!Xũũ) and //Kh'au//'e
- Ekoka-!Xun (Kung-Ekoka): 5000 speakers in Namibia and Angola
- Khwe (Kxoe): 4000 speakers in Namibia
- Naro: 4000 speakers in Namibia

The use of click sounds characterizes the Khoesan languages, though some clicks are adopted by some Bantu languages, such as Rugciriku. The following five primary clicks are common in Namibian Khoesaan languages. They are named according to their places of articulation: labial (⊙), dental (/), alveolar (!), palatal (ǂ), and lateral (//).

European Languages

Namibian European languages are those languages that originated from Europe, as they are not indigenous African languages. The main European languages spoken in Namibia are English, Afrikaans, German, and Portuguese. German, English, and

Afrikaans entered Namibia as official languages during the different colonial periods. German was the official language before World War I and is currently spoken by about 12 000 speakers. Although there is no substantial English-speaking community in Namibia, English became the official language after Namibia became independent in 1990 and is used widely as a second language, as well as in more formal, official, or written contexts.

Afrikaans, spoken as a first language by about 133 324 speakers, has been the established lingua franca of Namibia, but is losing that status since English was adopted as an official language. Afrikaans has a slightly different status than other European languages, as it can be regarded as a distinct (African) language, rather than a variety of Dutch, to which it is historically related; it has undergone much more changes than the Namibian varieties of English, German, or Portuguese and has an indigenous norm of its own, making it independent from Dutch in a different way from other European languages (see Maho, 1998). Furthermore, Afrikaans is the mother tongue of a number of speakers who are not ethnically Afrikaaners – for example, the Rehoboth Basters and the Coloreds – thus making the relation between language and ethnicity more complex.

Language Policy and Use

According to the language policy in Namibia, all languages are equal, except the official language, regardless of the number of speakers or the level of development of a particular language. The 1990 constitution identifies English as the official language (Article 3) and safeguards individuals' rights to "enjoy, practice, profess, maintain and promote any culture, language, tradition or religion" (Article 19).

Thirteen languages are used in primary education as languages of instruction, whereas English is usually the language of instruction in secondary education, with national languages being taught as subjects.

The University of Namibia offers courses in several national languages. Language standardization and development are conducted through different government agencies, such as language committees.

Although English also plays an important role in the media, the country's multilingual character is reflected in the print media, with daily papers or sections in English, Afrikaans, Oshiwambo, and Otjiherero. Television broadcasts are mainly in English, though the news is also broadcast in Otjiherero, Oshindonga, Oshikwanyama, Silozi, Rungwali, and Setswana.

Nanjio, Bunyiu (1849–1927)

S Watanabe, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Buddhologist and Sanskrit scholar. Nanjio Bunyiu was born as the third son of a priest in charge of a temple of the Ōtani branch of the Jōdo Shinshu sect (the True Pure Land sect) in Mino Province (now part of Gifu Prefecture) in 1849, about 20 years before the Meiji Restoration and the same year an English ship came to Uraga. When he was 18 years old, he was forced to join the Tokugawa Shogunate in fighting against the loyalists against the loyalists to the emperor. Two years later, however, the head temple of his

sect ordered his group to disband before the Meiji Restoration. He claimed in his later years that he, originally of delicate constitution, owed a long life free from any serious illness to these two years of military training.

He enrolled himself in Takakura College, and his scholarly eminence was recognized by many elder priest-scholars. He had been able to compose rhyming poems in classical Chinese since he was quite young. After studying for two years in Kyoto, he returned home and helped his father teach Chinese classics. Jinko, one of the most famous scholars of the sect, succeeded in adopting him after persistent efforts. He returned to Kyoto as an administrative officer of his sect, teaching Chinese Classics in the evening.

In 1872, the government published decrees concerning religion, which allowed Buddhist priests of all sects to marry (Nanjio's sect had permitted priestly marriage since its foundation) and ordered every Buddhist priest to take a surname. Bunyiu took as his surname Nanjio, which was the place name of his adoptive father's temple. Since the latter part of the 8th century, the so-called Dual Shinto system had allowed Buddhist priests to administratively control a large proportion of Shinto shrines, but the decree of 1868 concerning the separation of Shinto and Buddhism ordered these Buddhist priests to relinquish their traditional positions. A nationwide anti-Buddhist outburst started and continued until the decree of 1875 ordered that every religious sect be free and protected. Nanjio was an eyewitness to this period of religious turbulence, and his records are precious.

The highest priest of Nanjio's sect, who had visited Europe for two years, decided as soon as he returned home to send the two brightest young priests to Europe in order to study Sanskrit. Japanese Buddhists had been studying Buddhist sutras through Chinese translations since their first introduction to Japan in about 850 A.D. To acquire direct access to sutras in Sanskrit meant an event of revolutionary magnitude to Japanese Buddhism. In 1876, Nanjio went to Oxford to study Sanskrit under Friedrich Max Müller and worked with him, publishing many Sanskrit Buddhist texts and English translations. Returning to Japan in 1884, he taught at Tokyo University and later became president of the private university of his sect. He seems to have advised Baron Iwasaki to buy Max Müller's library. Among his numerous works, *The catalogue of the Chinese translation of the Buddhist Tripitaka* (*the Nanjō Nanjo? catalogue*) is the most famous.

Napoli, Donna Jo (b. 1948)

A Sacknovitz, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Although best known as a syntactician, Donna Jo Napoli's teaching areas include syntax, phonetics, phonology, morphology, historical and comparative linguistics, Romance studies, structure of Japanese, structure of American Sign Language, poetics, poetry workshops, dialogue, fiction writing workshops, writing for ESL students, and mathematical and linguistic analysis of folk dance. Napoli is also an award-winning creative writer, whose works include co-edited anthologies of poetry by linguists.

Napoli, both a U.S. and Italian citizen, was born on February 28, 1948. She received her B.A. in mathematics (1970), her M.A. in Italian literature (1971), and her Ph.D. in general and Romance linguistics (1973), all from Harvard University. She completed a postdoctoral year studying linguistics at MIT before becoming a lecturer in the departments of philosophy and Romance languages and literatures at Smith College in Massachusetts from 1973 to 1974. From 1974 to 1975, Napoli was a lecturer in the departments of mathematics and Romance languages and literatures at the University of North Carolina at Chapel Hill. She served as assistant professor of linguistics at Georgetown University in Washington, D.C. from 1975 to 1980. From 1980 to 1987, Napoli

sect ordered his group to disband before the Meiji Restoration. He claimed in his later years that he, originally of delicate constitution, owed a long life free from any serious illness to these two years of military training.

Napoli, Donna Jo (b. 1948)

A Sacknovitz, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Although best known as a syntactician, Donna Jo Napoli's teaching areas include syntax, phonetics, phonology, morphology, historical and comparative linguistics, Romance studies, structure of Japanese, structure of American Sign Language, poetics, poetry workshops, dialogue, fiction writing workshops, writing for ESL students, and mathematical and linguistic analysis of folk dance. Napoli is also an award-winning creative writer, whose works include co-edited anthologies of poetry by linguists.

Napoli, both a U.S. and Italian citizen, was born on February 28, 1948. She received her B.A. in mathematics (1970), her M.A. in Italian literature (1971), and her Ph.D. in general and Romance linguistics (1973), all from Harvard University. She completed a postdoctoral year studying linguistics at MIT before becoming a lecturer in the departments of philosophy and Romance languages and literatures at Smith College in Massachusetts from 1973 to 1974. From 1974 to 1975, Napoli was a lecturer in the departments of mathematics and Romance languages and literatures at the University of North Carolina at Chapel Hill. She served as assistant professor of linguistics at Georgetown University in Washington, D.C. from 1975 to 1980. From 1980 to 1987, Napoli

taught linguistics at the University of Michigan at Ann Arbor, where she both earned tenure (1981) and became a full professor (1984). Napoli is currently a professor of linguistics at Swarthmore College in Pennsylvania, a position she has held since 1987.

Napoli has been a visiting lecturer at numerous universities in the United States, Africa, Asia, and Australia.

In the field of linguistics, Napoli has authored, co-authored, and edited a total of 11 books and more than 50 articles ranging from theoretical linguistics to practical matters in language structure and use. Within the area of syntax, her works focus primarily on Romance languages, particularly Italian. Her dissertation, published in 1976, focused on an analysis of reflexive, inchoative, and indefinite subject sentences in Modern Standard Italian, particularly the two clitic *si's* of Italian, one generated by the transformation rule REFLEXIVE, the other by the transformation rule si-INSERTION. Napoli has also written on such topics in Italian syntax as infinitival relatives, variations on relative clauses, evidence for syntactic analogy based on adverbs and prepositions, syntax of word-initial consonant germination, subject pronouns, clitic climbing, complementation, comparative structures, inflected prepositions, secondary resultative predicates, reflexivization across clause boundaries, and evaluative affixes.

Within English syntax, Napoli has researched definites in there-sentences, initial material deletion, comparative ellipsis, comparative 'rather,' analysis of null complement anaphora, and verb phrase deletion.

Anaphoric processes have also interested Napoli. In *Predication theory: a case study for indexing theory* (1989), Napoli claimed that predication and role players are primitives that are not configurationally defined. She sought to extend predication coindexing principles into a general indexing theory, suggesting that indexing principles between predicates and their subject role players should and could be extended to handle coindexing between anaphors and their antecedents. This theory illustrated that the indexing relation was semantic in nature, that predicative NPs were not necessarily exceptions to binding theory, and that anaphors and predicates were a single phenomenon.

In addition, Napoli has researched prosody. Napoli edited a 1978 volume (*Elements of tone, stress, and intonation*; Napoli, 1978), based on an interest group she organized for the 1977 Georgetown University Round Table, which explored tone, stress, and intonation, and the ways in which these prosodic elements are sensitive to syntactic and semantic information. She has applied metrical theory to analysis of the metrics of Italian nursery rhymes and Robert Frost's poetry and co-authored a book titled *A prosodic template in historical change: the passage of the Latin second conjugation into Romance* (Stuart and Napoli, 1994).

Recently, Napoli has studied American Sign Language (ASL) and the education of deaf children, on which she has co-authored numerous papers. In the 'Exploitation of morphological possibilities in signed languages: comparison of American Sign Language with English' (Fernald and Napoli, 2000), Theodore Fernald and Napoli explored how ASL shares derivational and inflectional morphological processes with spoken languages, claiming that ASL has an extensive nonderivational, noninflectional morphology involving phonological alternation. They posited 'ion-morphs,' phonologically incomplete lexical items that bond with other compatible ion-morphs, that draw lexical items into 'families' of related signs (Fernald and Napoli, 2000). They found that ASL makes little use of concatenative affixation, common among spoken languages, which they explained by the slowness of movement of manual articulators compared to speech articulators, and the perceptual robustness of the manual articulators to the visual system. In 'Morpheme structure constraints on two-handed signs in American Sign Language: notions of symmetry,' (Napoli and Wu, 2003), Napoli and Jeff Wu dealt with notions of mathematical symmetry that play a role in the well-formedness of signs. In 2004, Napoli also organized the conference, 'Signs and Voices: Language, Arts, and Identity from Deaf to Hearing' (2004).

Napoli's passion for teaching linguistics is evident in her instructional texts. The stated goal of her co-authored book, *Syntactic argumentation* (Napoli and Rando, 1979), which included 12 articles, each preceeded by an explanation of historical context and followed by questions, comments, and references, was to foster the habit of reading articles critically and evaluating the reasoning. Similarly, her 1993 book, *Syntax: theory and problems,* challenged readers new to syntactic analysis to develop a theory based on the data provided. In both *Syntax* and *Linguistics: an introduction* (1996), Napoli stressed that one can only learn linguistics by looking at data and solving problems. Napoli recently co-authored *L'animale parlante* (Nespor and Napoli, 2004) with Marina Nespor, an introduction to the field of linguistics in Italian.

Although Napoli's recent work *Language matters: a guide to everyday questions about language* (2003), which explored language issues in daily life by addressing misconceptions about language, was intended for the general public, the public is probably most familiar with Napoli in her role as an

award-winning author. Napoli, the mother of five children, Elena, Michael Enzo, Nicholas Umberto, Eva, and Robert Emilio, who all share her husband Barry Furrow's last name, has authored picture books, children's and young adult novels, stories, and poems, many of which have received major awards in creative writing. Her writing ranges from contemporary fiction to fantasy to historical novels. She also writes mathematics tales and science tales as well as books geared toward helping deaf people learning to read. In addition, Napoli has written several essays about children's literature and writing for children. Napoli has also co-edited and contributed to five poetry anthologies, containing poems written by linguists including Deborah Tannen and Dell Hymes, the most recent of which is *Tongue's palette: poetry by linguists* (Sunshine and Napoli, 2004).

Narrative and Discourse Impairments

K Lundgren, Boston University School of Medicine, Boston, MA, USA
H Brownell, Boston University School of Medicine, Boston College, Chestnut Hill, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Communication between people takes place over many channels and relies on an array of component abilities, including phonological, syntactic, and lexical semantic competence. Accordingly, many communication impairments can be understood best in terms of these highly constrained, rule-governed domains. However, speakers also invariably use sentences or utterances in context to convey thoughts and goals to a listener. The use of utterances in context constitutes the domain of discourse. As will become clear from this article, discourse and discourse impairments represent fundamental aspects of human communication. We examine in turn several topics bearing on impaired discourse resulting from acquired brain injury in adults. We start by mentioning some caveats to the findings reviewed and then provide summaries of representative impairments in production and then comprehension of conversational and narrative discourse. We conclude by mentioning some topics that fall beyond the scope of this article but that are nonetheless related to discourse.

Caveats

Discourse should be treated as distinct from other levels of language description, but in practical terms it is difficult to separate discourse-level impairments from traditional aphasic impairments at the levels of phonology, syntax, and lexical semantics because so much of language is based on words and sentences. As a result, much of the neuropsychological

Discourse should be treated as distinct from other levels of language description, but in practical terms it is difficult to separate discourse-level impairments from traditional aphasic impairments at the levels of phonology, syntax, and lexical semantics because so much of language is based on words and sentences. As a result, much of the neuropsychological

literature on discourse has addressed impairments in the absence of aphasia in patients with unilateral right-sided brain damage due to stroke (see reviews by Code, 1987; Goodglass, 1993; Joanette *et al.*, 1990; Myers, 1999; Tompkins, 1995) and in patients with unilateral or bilateral (often prefrontal) damage due to traumatic brain injury that lies outside of the classical language zones (McDonald, 1993). The reason is that an initial goal for researchers in this field was to establish the existence and relevance of discourse impairments as distinct from aphasia. It was clinically important to characterize the subtle but very real communication deficits of patients without aphasia. It was theoretically important to identify discourse-level impairments that corroborate the distinction between discourse and other levels of language description.

Partly as a function of this history, it is necessary to use caution when interpreting the literature on discourse impairments. Many studies compare the performance of nonaphasic brain-injured patients against the performance of non-brain-injured control participants. This experimental design leaves unspecified the precise localization of function related to a deficit: Comparable problems might result from damage to other regions of the brain as well. In addition, good performance on any discourse task requires several component skills and therefore relies on the contributions of several cognitive as well as neurological systems. Disruption to any component skill could result in superficially similar declines in task performance. In addition, there is considerable variation in symptoms exhibited by different patients with apparently similar lesions. For example, a large proportion of patients with right hemisphere damage (approximately half by one estimate) show no obvious communication deficit (Joanette *et al.*, 1991). Some researchers have responded to this heterogeneity across patients by advocating the use of case studies rather than group studies for cognitive neuropsychological investigations (Caramazza, 1986). Studies that report comparisons between groups of patients characterized by damage to different areas of the brain support stronger claims concerning localization of function. Even in these studies, patient groups are often defined in terms of diffuse damage or in terms of focal lesion anywhere within large areas of cortex. Precise localization of discourse functions is not yet established.

In this article, we use the term LHD to denote adult patients with unilateral, left hemisphere brain damage that is accompanied by aphasia. The corresponding terms RHD (unilateral right hemisphere damage), TBI (traumatic brain injury), and SDAT (senile dementia of the Alzheimer type) are used to denote the absence of marked aphasia.

Production Impairments

Discourse production can be a viewed at a number of levels; however, most studies have analyzed discourse production at either a microlinguistic (intrasentential) or a macrolinguistic level (suprasentential). Microlinguistics refers to linguistic units (phonology, semantics, and syntax) at the word or sentence level. Macrolinguistics refers to larger pieces of language units analyzed in relation to types of nonlinguistic textual and extratextual factors.

In this section, we discuss production deficits that occur beyond the sentence level in two different types of discourse genres: conversational exchange and oral narrative. The analysis of conversational exchange has its roots in ethnomethodology, a branch of sociology that is concerned with everyday social interaction and specifically with how individuals within a society come to know, and to know in common, what they are doing and the circumstances in which they are doing it (Heritage, 1984). The field of conversational analysis, as it relates to disordered language use, is a relatively new and complex field of inquiry that involves linguistic, cognitive, and social domains of human interaction in brain-damaged patients.

In contrast, the analysis of oral narrative is deeply rooted in linguistics. The study of oral narratives has focused primarily on formal structure using story grammars (Mandler and Johnson, 1977; van Dijk, 1980) and only recently has incorporated the relationship between story grammar and other world knowledge (Black and Wilensky, 1979).

Analysis of discourse production, with its rich interaction between the linguistic, cognitive, and social domains, has the potential to influence the ways in which we assess and treat patients. However, as is evident from this article, this new field needs a uniform application of elicitation procedures and analytic frameworks to support comparisons of discourse performance within and across diagnostic groups.

Conversational Discourse

Communicative exchange depends on social rules and behaviors (Searle, 1969). A successful conversation requires basic linguistic ability and also the ability to maintain a topic, sensitivity to a conversational partner's knowledge and needs, appropriate turn-taking, and accurate monitoring of the emotional dimensions of a message. Discourse further requires constant

interpretation and prediction as a conversation progresses. Any individual utterance within an exchange reflects the preceding context and refines or redirects that context and, in some sense, anticipates the ultimate direction or goal of the conversation. Heritage (1984) described conversational utterances as being both 'context-shaped' and 'context-renewing.' Finally, conversation is an essential means of establishing and maintaining social relationships. Despite the central role played by conversation in daily life, only a relatively small number of studies have focused on conversational discourse in adults with acquired brain injury. The results of these studies suggest that the type of discourse disruption depends on the type of brain damage; however, it is difficult to derive firm conclusions because the studies used different elicitation procedures and approaches to analysis.

One body of studies on conversational skills has focused on aphasic patients indicates primary disruption in conversation at the microlinguistic level: Disturbed phonological, semantic, and/or syntactic-level skills can appear simultaneously with a preservation of macrolinguistic abilities such as informational structure (Glosser and Deser, 1990; Ulatowska and Chapman, 1994) and speech acts in some patients and a restriction of communicative functions in others (Kasher *et al.*, 1999; Wambaugh *et al.*, 1991).

Studies based on other populations often reveal a contrasting pattern with less impairment at the level of microstructure. For example, TBI patients show difficulties with the macrolinguistic structure of language characterized by difficulty with topic introduction and management and providing more information than requested about a topic (Coelho *et al.*, 2002).

Results from studies of SDAT patients similarly reveal disruption at the macrolinguistic level of discourse with fewer elaborations on the topic (Garcia and Joanette, 1994; Glosser and Deser, 1990) impaired cohesion, and inappropriate topic shifts, topic introduction, and topic development (Mentis *et al.*, 1995; Ripich and Terrell, 1988). In addition to these topic management disruptions, SDAT patients resort more often to nonverbal responses.

RHD patients also display more difficulty with conversation at the macrolinguistic level; however, the reason for the disruption has not been clearly delineated. Kennedy *et al.* (1994) evaluated first-encounter conversations between a speech–language pathologist and RHD patients in order to examine turn-taking skills and topic manipulation. Although results revealed large variation in conversational skills within the RHD group, characteristic RHD impairments were evident in the number of turns taken. RHD conversations contained more turns than those of control participants but fewer requests for information from the conversational partner and more statements about themselves. In addition, the RHD group produced far fewer words per turn than did the NBD group. In another first-encounter conversation study (Kennedy, 2000), the introduction of topic scenes (things that get talked about) was compared to assess similarities between the RHD and the NBD groups in incidence, type, and location of topic scenes within a discourse. During the termination phase of a conversation, RHD patients produced larger proportions and different types of topic scenes than are typical of a first-encounter conversation, perhaps due to suppression/inhibition deficits or misinterpretation of subtle indicators used to wrap up a conversation. In addition, Chantraine *et al.* (1998) reported varying degrees of impairment in how well RHD patients take into account knowledge shared between themselves and a listener.

Narrative Discourse

Oral narratives constitute the genre used most frequently to study discourse skills after brain damage. Investigation of narratives can concentrate on an individual's microstructural skills using, for example, word counts and indices of intrasentential grammar and intersentential cohesion, as first proposed by Kintsch and van Dijk (1978), or on a person's global or macrostructural abilities linked to story grammars, as first proposed by Mandler and Johnson (1977), and to the overall goal, plan, theme, or topic of a narrative. (Models of narrative discourse such as story grammars are more structured than are descriptions of conversational discourse.) Although results of studies examining narrative production are also difficult to interpret due to the wide range of sampling techniques and analysis measures reported, some patterns parallel those found in studies of conversation.

Studies of people with aphasia indicate narrative disruption at the microlinguistic level, with phonological, semantic, or syntactic skills at greatest risk and with the macrostructural skills fairly preserved (Glosser and Deser, 1990).

Results from studies of TBI indicate disruption generally at the macrolinguistic level rather than the microstructural level. TBI patients produce a normal number of episodes in a story-retell task but produce fewer episodes in a story-generation task (Liles *et al.*, 1985). Disrupted production of cohesion ties and difficulty with referential cohesion and logical coherence have also characterized narrative discourse in

individuals with TBI (Mentis and Prutting, 1989). The specific disruptions observed vary as a function of the elicitation procedure: Logical coherence deficits have been found using story-retell tasks and referential cohesion deficits with picture-elicitation tasks.

Performances of SDAT patients did not differ significantly from those of age-matched control groups in terms of microlinguistic measures during narrative production. However, dementia is associated with semantic impairments as well as impairments at the macrolinguistic level defined in terms of cohesion (Glosser and Deser, 1990).

RHD patients similarly exhibit macrolinguistic deficits; however, there does not appear to be agreement regarding the type or severity of deficit. A number of investigators have suggested subgroups of RHD patients based on discourse performance (Joanette *et al.*, 1986), with some RHD subjects performing somewhat like the normal control group. However, Cherney *et al.* (1997) suggested that the presence and persistence of unilateral neglect may be a factor in determining subgroups and may be related to disruptions in narrative discourse.

Comprehension Impairments

Narrative Discourse

Using Context to Guide Comprehension of Single Sentences The general statement that brain injury limits patients' understanding of discourse and linguistic context is not controversial. However, there are many differences across patient populations that underscore the composite nature of discourse. Discourse rests in large part on comprehension of single sentences, which is limited by most forms of aphasia due to left hemisphere brain damage but is often relatively spared subsequent to RHD or TBI, which often leaves a patient without marked aphasia. One issue is to determine how discourse impairments can differ from symptoms of aphasia, even if many conclusions are still subject to revision. For example, brain injury often disrupts a patient's ability to use context to build a complete understanding of a discourse. However, the ability to use context effectively varies as a function of the nature of the task. Leonard *et al.* (1997), for example, showed that RHD patients are typically able to establish at least some forms of discourse connections across sentence boundaries: RHD patients perform very well comprehending ambiguous pronouns whose antecedents are constrained by verb meaning, and they can establish cohesive ties that span sentence boundaries. On the other hand, the literature contains reports of impaired use of intrasentential context. Grindrod and Baum (2003), for example, reported that both aphasic LHD and nonaphasic RHD patients exhibited different types of abnormal use of within-sentence or 'local' context to guide lexical access. Briefly, neither LHD nor RHD patients showed normal effects of context at the briefest time intervals. At longer time intervals, the RHD patients showed some effects of context but still made less use of context than nonbrain-injured participants. Tompkins *et al.* (1997) argued that although aspects of lexical access may be spared subsequent to RHD, postaccess processing, such as suppression of contextually irrelevant meaning within a sentence, appears disrupted.

When the precise timing of inferences based on context is not the focus, studies document that LHD, aphasic patients do relatively better, and RHD and TBI patients do relatively worse. For example, Hough *et al.* (1989) showed that aphasic patients could use linguistic and nonlinguistic predictive context to facilitate comprehension of target sentences. Using longer discourse samples, Hough (1990) illustrated how RHD limits a person's ability to infer a gist or theme from multisentence texts. Whereas RHD patients' comprehension was clearly disrupted when the theme of a text was not presented until the end of the stimulus passage rather than at the beginning, LHD patients' comprehension was much less disrupted by the delayed presentation. Joanette *et al.* (1986) similarly reported that RHD patients were deficient in terms of the inferential aspects of recall of a more complex story.

Short story jokes provide a useful vehicle for examining discourse comprehension impairments because the form for the genre is well established. A standard analysis rests on two components: incongruity and coherence. A standard joke begins with a set up or context that plays on a listener's cultural knowledge: The body of a joke makes very clear what should happen in a normal situation. The punch line of a joke is incongruous in that it violates those expectations and is surprising. The humor of a joke is tied to the listener being able to understand the incongruity of the punch line and perform an inference that shows how the punch line might in fact relate to the body of the joke on some alternative analysis. Bihrle *et al.* (1986) reported that RHD patients retained knowledge of how jokes worked: They were able to choose candidate punch lines that were incongruous. However, the RHD patients showed reduced ability to carry out the inference necessary to identify the correct punch line from among a set of incongruous alternatives. (Other work has documented analogous inference deficits in RHD patients using nonhumorous materials, which rules out any explanation tied to emotion.) When presented with multiframe,

captionless cartoon jokes, LHD patients were better able than RHD patients to identify correct endings to humorous narratives. Thus, some aspects of impaired discourse can be dissociated from aphasia.

Conversational Discourse and Nonliteral Language

Metaphor and Idioms Language is often nonliteral in the sense that the intended or speaker's meaning is different from a completely conventional, literal, or denotative interpretation of a word or utterance. Examples of nonliteral language include metaphor and idioms, sarcasm, and indirect requests. Of these, metaphor and idioms rest at the bridge between lexical semantics and discourse. We include metaphor here because deficits in the literature are reported for the same patient populations (RHD patients) as are other more clear discourse-level forms of speech.

One straightforward investigation of metaphor and idiom comprehension by unilaterally LHD and RHD patients was reported by Van Lancker and Kempler (1987). One task was an idiom comprehension task in which patients had to listen to a common (frozen) idiom such as "He's turning over a new leaf" and select the appropriate pictorial representation from a set of four that included a picture of a man with a halo tossing a liquor bottle and a Playboy magazine into the trash (correct), a man raking leaves (literally correct but inappropriate), an angry defiant convict sitting in a prison bunk (opposite or related to the appropriate meaning of the idiom), and an unrelated item (people sitting in a movie theater). In another condition, patients listened to novel sentences such as "When the happy girl pushes, the angry boy swings" and had to select the correct depiction from a set of four that represented permutations of grammatical roles (an unhappy girl pushing a boy, a boy pushing a girl, etc.). The major result was that the RHD patients performed worse than the aphasic patients in the idiom condition and better than the LHD patients in the syntactically demanding novel sentence condition. The most important results indicated that impairment on this form of nonliteral language comprehension appeared to be specific to right hemisphere lesion and not to left hemisphere lesion. Other work has broadened the scope of the RHD deficit in interpreting nonliteral language to include the interpretation of single words such as 'warm' used to mean not only high temperature but loving (Brownell *et al.*, 1990).

Interpretation of Nonliteral Utterances in Context Brain-injured patients' use of context as a guide to nonliteral utterance interpretation has been most thoroughly examined using indirect speech acts, such as indirect requests and sarcasm. Requests can take a range of forms, from the most direct ("Get out of here") to less direct ("Would it be possible for you to leave us alone for a while?") and mere hints ("It seems a little crowded in here"). Increasing degrees of indirectness can be used to increase the politeness of a request by leaving more up to the hearer's discretion. With respect to indirect requests, Foldi (1987) suggested that RHD patients exhibit a tendency to focus on literal interpretations of utterances and that LHD aphasic patients fare relatively better at extracting a pragmatically appropriate interpretation. Stemmer and colleagues (1994) presented a more detailed theoretical guide to assessing the performances of RHD patients. They reported that the RHD patients tested were deficient in evaluating the level of directness of requests as well as the degree of politeness and the likelihood of occurrence of a request form. The nature of the deficits outlined is more interpretational and social than based on linguistic analysis of the component sentences.

A similar line of investigation has explored comprehension of sarcasm and irony, in which a host of meanings can be conveyed by stating the opposite of what is literally true. For example, the utterance "You played a great game" spoken to someone who has just performed terribly can convey a negative intent. Alternatively, a literally false utterance could be simply a mistake or even a white lie designed to protect a hearer's feelings. Similar to the work on indirect requests, investigations of sarcasm comprehension have shown that most RHD patients are able to decode the literal meanings of utterances and to realize when an utterance is literally false. It is deriving the appropriate pragmatic interpretation that presents difficulty because doing so rests on inferential ability and on attention to the social as well as linguistic context. Kaplan *et al.* (1990) varied the relationship (hostile or friendly) between a speaker and hearer in a reported conversation and also the literal truth of a comment made about either a good or a poor performance. Nonbrain-injured controls interpreted utterances in terms of the relationship and the conventions of politeness. For example, the comment "You played very well" uttered after a terrible performance was interpreted as a white lie in the context of a friendly relationship and as a sarcastic and nasty comment in the context of a hostile relationship. The RHD patients as a group were less able to make those sorts of distinctions; the RHD patients were able to arrive at similar conclusions but less reliably. It is worth noting that the role of speech prosody was minimized in this study. Other

work has explored similar deficits in TBI patients (McDonald and Pearce, 1996) or has also examined tone of voice (Tompkins and Mateer, 1985).

Summary

This article listed a range of language-based impairments in discourse and, as shown by the representative studies cited, discourse impairments can usefully be discussed and partially understood in terms of a person's appreciation of linguistic and social context. However, several other domains within language and cognition contribute to success in the realm of discourse. Although they fall outside the scope of this article, these topics have great relevance to understanding how brain injury can affect discourse performance and thus warrant mention. The most closely related is speech prosody, which can be used to convey a host of linguistic, pragmatic, and affective content (for a review, Baum and Pell, 1999). Brown and Levinson's (1987) work on politeness provided a different perspective that links linguistic forms to social considerations such as relative social power and autonomy. Theory of mind – that is, the ability to use other people's thoughts, emotions, and beliefs as a guide to understanding their words and actions – is a burgeoning area of investigation that informs interpretation of discourse impairments (for a review, see Baron-Cohen *et al*., 2000). Finally, there are efforts to account for discourse-related impairments under different theoretical umbrellas, such as 'coarse semantic coding,' weak central coherence, executive dysfunction, theory of mind, relevance theory, or working memory (Beeman and Chiarello, 1998; Martin and McDonald, 2003; McDonald, 1999; Tompkins *et al*., 1994). This breadth of topics reflects the complex nature of discourse and its importance to understanding human communication.

Narrative: Cognitive Approaches

D Herman, Ohio State University, Columbus, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction: The Scope of Cognitive Narrative Analysis

Study of the cognitive dimensions of stories and storytelling has become an important subdomain within the field of narrative analysis. Concerned both with how people understand narratives and with narrative itself as a mode of understanding, cognitive approaches have been brought to bear on stories in a variety of media. Studies range from cognitively inflected accounts of narrative perspective in fictional and nonfictional texts (van Peer and Chatman, 2001), to inquiries into narrative as a resource for navigating and making sense of computer-mediated environments (Ryan, 2001), to intermedial research suggesting that narrative functions as a cognitive 'macroframe' enabling interpreters to identify stories or storylike elements across any number of semiotic media, literary, pictorial, musical, and other (Wolf, 2003). Equally various are the disciplinary traditions from which cognitive approaches borrow descriptive and explanatory tools. Source disciplines include cognitive linguistics; pragmatics; discourse analysis; narratology; communication theory; anthropology; stylistics; cognitive, evolutionary, and social psychology; rhetoric; computer science; literary theory; and philosophy.

It should not be surprising that, given the range of artifacts and media falling under their purview, their richly interdisciplinary heritage, and the varying backgrounds and interests of their practitioners, cognitive approaches to narrative at present constitute more a set of loosely confederated heuristic schemes than a systematic framework for research on stories. Nonetheless, for descriptive convenience I use the term *cognitive narrative analysis* (hereafter CNA) as a blanket designation for all the approaches discussed in this article – even though CNA in fact encompasses a number of distinct tendencies, each with a particular theoretical emphasis, battery of concepts, and preferred investigative method.

The second section of this article contextualizes CNA by sketching two overarching research developments from which it took rise. The third section then surveys specific analytic paradigms that have helped shape CNA; the section traces forward the influence of these paradigms to provide an overview of some of the main trends within CNA as currently practiced. Finally, after discussing criticisms leveled against the enterprise of CNA, the fourth section outlines areas of concern that can be viewed as targets for future research activity in the field.

Contexts for CNA

Two related trends have functioned as precipitating events for the emergence of CNA. The first is the 'narrative turn' that began to unfold across many disciplines in the mid to late 1960s, in part as a result of the development of structuralist narratology in France. Noting that narratives can be presented in a variety of media, communicative situations, cultural traditions, and genres, structuralists such as Barthes (1977 [1966]) argued explicitly for a cross-disciplinary approach to the analysis of stories. In large part, Barthes's call for an interdisciplinary approach to narrative was answered in the years following the heyday of structuralism. Stories became at once a metaphor more or less loosely applied to disparate content areas ('stories of nationhood,' 'narratives of gender,' etc.), an object of inquiry in multiple field of study, and an explanatory framework for making sense of events defined by their position in an unfolding time-course (Mink, 1978).

Second, this cross-disciplinary concern with stories has facilitated an especially momentous convergence of humanistic and cognitive-scientific research on narrative. On the one hand, in the constellation of disciplines associated with the cognitive sciences (including linguistics, neuroscience, psychology, computer science, and philosophy), scholars have shown an increasing willingness to take on ever more complex and richly situated narratives (see, e.g., Bamberg, 1997; Emmott, 1997; Ochs and Capps, 2001). Researchers in these fields have begun to embrace the challenge of characterizing how readers or listeners process extended natural-language narratives, as opposed to the short, artificially constructed narratives designed by early cognitive theorists. On the other hand, humanists studying various forms of verbal art, and in particular narratives, have become increasingly open to and knowledgeable about developments in the cognitive sciences (Abbott, 2001; Richardson and Steen, 2002). Indeed, the central aim of literary CNA and of related endeavors whose focus extends beyond narrative, including cognitive semiotics (Fastrez, 2003), cognitive poetics (Stockwell, 2002; Gavins and Steen, 2003), and cognitive stylistics (Semino and Culpeper, 2002), is to discover ways of reconnecting the study of literary narratives (among other semiotic artifacts) with the study of language and mind. These initiatives thereby seek to promote

new, synergistic interactions among areas of inquiry that have remained overcompartmentalized up to now.

Varieties of CNA: Paradigms and Practices

At a more granular level of description, current-day practices in CNA can be traced back to a number of (partly overlapping) research paradigms. Three of the relevant paradigms were roughly coeval, coming into prominence in the 1960s and 1970s: structuralist narratology, sociolinguistic approaches to narrative (among other forms of talk) as a contextually situated practice, and efforts within psychology and artificial-intelligence research to model the cognitive infrastructure of narrative, i.e., the mental equipment that enables people to design and interpret stories. Subsequent researchers built on these precedents to generate ideas whose pertinence for CNA is only now beginning to be grasped. Because of the limited scope of this entry, I single out two later paradigms (or groups of paradigms) as especially salient. On the one hand are the frameworks developed under the auspices of cognitive linguistics and cognitive grammar, which characterize embodied human experience as the basis for all language structure and use. On the other hand are models of 'the discursive mind' (Harré and Gillett, 1994), which are sometimes associated with what has been called the 'second cognitive revolution' (Harré, 1992; Harré and Gillett, 1994). This work grounds humans' intelligent activity in the situated production of talk rather than in the minds of solitary cognizers. Space limitations require that my synopsis exclude other important research – e.g., work in evolutionary psychology, neuroscience, and cognitive anthropology – that would need to be discussed in a fuller account of CNA.

Structuralist Narratology: Codes and Cognition

Tzvetan Todorov coined the term *la narratologie* in 1969 to designate what he and other Francophone structuralists (e.g., Roland Barthes, Claude Bremond, Gérard Genette, and A.-J. Greimas) conceived of as a science of narrative modeled after the 'pilot-science' of Saussure's structural linguistics. By analogy with Saussurean structuralism, the early narratologists sought to account for the underlying code (*la langue*) supporting the production and interpretation of particular narrative 'messages' (*la parole*).

Emphasizing the need for a systematic investigation of the narrative code in whatever setting, medium, or genre it obtains, structuralist narratology prepared the ground for interdisciplinary research on stories, including CNA. Moreover, structuralists such as Barthes anticipated the work on knowledge representations reviewed below. Barthes (1977 [1976]) suggested that people make sense of narratively organized sequences of events by subsuming particular clusters of events under 'essential headings' of 'the narrative language within us' (Barthes, 1977 [1966]) – a language or semiotic code which Barthes would eventually reanalyze into five interlocking subcodes, including the proairetic code (used to parse event-sequences into patterns of action) and the semic code (used to interpret narrated events as anchored in characters' traits and dispositions). As discussed later, arguments along these lines set an important precedent for some strands of CNA (e.g., Cook, 1994; Herman, 2002: 85–113; Stockwell, 2002: 75–89). Yet the early narratologists were hamstrung by their own structuralist methodology; their use of the 'pilot-science' of Saussure's code-centered linguistics was already out of phase with emergent developments in language theory and related fields of study. Focusing on how the language system is anchored in particular contexts of use, these new developments provided important underpinnings for CNA. Theorists began to concern themselves with the material circumstances of narrative transactions, not just the structural properties of narrative viewed as a semiotic code; in the process analysts acquired new tools for describing cognitive dimensions of storytelling situations.

Contextualism (I): Thinking through Narrative Transactions

For researchers concerned with the social contexts of language use, 'messages' or utterances (including the extended utterances that take narrative shape) should be viewed not as manifestations of a code that preexists all communicative acts but, rather, as an interactional achievement, negotiated by participants using an inherently variable linguistic code in situated contexts. Fostering the creation of subfields such as linguistic pragmatics, discourse analysis, and sociolinguistics, this contextualist approach to language-in-use also gave birth to Labov and Waletzky's (1967) pathbreaking account of personal-experience narratives, which in turn spawned an extensive body of research in this area (see Bamberg, 1997, for a useful overview).

The model outlined by Labov and Waletzky (1967) forged an approach to studying stories-in-use that could accommodate structural, contextual, and cognitive factors. Establishing what remains a much-relied-on vocabulary for labeling the macro-units of personal-experience narratives (abstract, orientation, complicating action, evaluation, resolution, coda), the model had important implications for CNA along two

dimensions. First, it identified linguistic structures tending to surface in each of these macro-units and suggested that interpreters monitor the discourse for signs enabling them to 'chunk' what is said into units-in-a-narrative-pattern. Second, at the interactional level, the framework stressed the importance of 'point,' i.e., the need for storytellers to provide various sorts of cues (e.g. expressive phonology and evaluative lexical items) that enable interlocutors to infer the *raison d'être* of the narrative, or why it is worth accommodating within an ongoing discourse. The model thus targeted multiple kinds of inferential activity engaged in by storytellers and their interlocutors. At issue are inferences about part-whole and part-part relations among story components, as well as judgments about the appropriateness of narrative tellings in particular kinds of communicative environments.

Building on Labov's and Waletzky's work, subsequent theorists have thrown additional light on cognitive features of narrative transactions, some of them arguing for an even more rigorously contextualist approach (again, Bamberg, 1997, provides an overview). Students of narrative working in the conversation-analytic tradition, for example, argue that theories about the cognitive and communicative properties of narrative cannot be adduced *a priori* and imposed as a one-size-fits-all template on all narrative interactions; rather, they must emerge on a case-by-case basis from the disposition or sequencing of structural elements of stories told during interactions unfolding within particularized settings. Whatever their special emphasis, however, studies within the contextualist paradigm underscore how narrative facilitates intelligent behavior. Stories support the (social) process by which participants determine and evaluate the meaning of events, enable the distribution of knowledge via storytelling acts more or less widely separated in time and space from the experiences that they recount, and assist with the regulation of communicative behaviors on a turn-by-turn basis, such that participants can coordinate behaviors required to engage in knowledge-yielding and-conveying talk. The later section on contextualism (II) details how research informing current work in CNA extends and enriches this 'first-wave' contextualism by incorporating ideas from other traditions, e.g., Vygotsky's (1978) account of the social origins of human intelligence.

From Story Grammars and Knowledge Representations to CNA

In the 1970s and 1980s, both cognitive psychologists and artificial-intelligence researchers developed hypotheses about cognitive structures underlying the production and understanding of narrative. This work bears a family resemblance to structuralist accounts of narrative sequences, but features a more explicit and productive nomenclature that continues to shape the practice of CNA today.

Story Grammars On one front, researchers such as Mandler (1984) postulated the existence of what they characterized as cognitively based story grammars or narrative rule systems. Such grammars were cast as formal representations of the cognitive mechanisms used to parse stories into sets of units (e.g., settings and episodes) and principles for sequencing and embedding those units (for a fuller discussion, see Herman, 2002: 10–13). As Mandler put it, "[t]he contention of all story grammars is that stories have an underlying, or base, structure that remains relatively invariant in spite of gross differences in content from story to story. This structure consists of a number of ordered constituents" (1984: 22).

Although the effort to develop full-fledged story grammars is a thing of the past in cognitive psychology and no longer occupies pride of place in CNA, narratological adaptations of the story-grammar enterprise by scholars such as Prince (1973) and Pavel (1985) have had a lasting impact on narrative analysis in general and CNA in particular. Furthermore, current-day work in artificial intelligence builds on the earlier work: a number of theorists are attempting to develop both story-recognizing and story-generating algorithms (Sengers and Mateas, 2003). This research continues the effort to create formal representations of the mind's capacity to design and interpret stories, testing the adequacy of those formal models through computer implementations.

Knowledge Representations Roughly contemporaneously with the advent of story grammars, research in artificial intelligence also began to focus attention on the cognitive basis for creating and understanding stories. Schank and Abelson's (1977) foundational work explored how stereotypical knowledge reduces the complexity and duration of many processing tasks, including the interpretation of narrative. Indeed, the concept of 'script,' i.e., a type of knowledge representation that allows an expected sequence of events to be stored in the memory, was designed to explain how people are able to build up complex interpretations of stories on the basis of very few textual or discourse cues. Whereas the term *scripts* was used to refer to kinds of world-knowledge that generate expectations about how sequences of events are supposed to unfold, *frames* referred to

expectations about how domains of experience are likely to be structured at a given moment in time.

Although subsequent research on knowledge representations suggests the limits as well as the possibilities of the original frame and script concepts (see Sternberg, 2003, for a critical review), practitioners of CNA continue to draw on this work as both a model and a metaphor for understanding how particular features of narrative discourse cue particular kinds of processing strategies. Some theorists have focused on how experiential repertoires, stored in the form of scripts, enable readers or listeners of stories to 'fill in the blanks' and assume that if a narrator mentions a masked character running out of bank with a satchel of money, then that character has in all likelihood robbed the bank in question. Analysts have also discussed how literary narratives in particular involve processes of script recruitment, disruption, and refreshment (Cook, 1994; Herman, 2002: 109–113; Stockwell, 2002: 75–89), depending on how critically and reflexively the narratives relate to prevailing scripts.

Three especially noteworthy extensions of the original research can be mentioned here. In Jahn's (1997) proposal for a cognitive narratology, higher-order knowledge representations or frames enable interpreters of stories to disambiguate pronominal references, decide whether a given sentence serves a descriptive or a thought-reporting function (e.g., depending on context *the train was late* might either be a thought mulled over by a character or part of the narrator's own account of the narrated world), and, more generally, adopt a top-down as well as a bottom-up approach to narrative processing. A frame guides interpretation until such time as textual cues prompt the modification or substitution of that frame. Along similar lines, Emmott (1997) focuses on how what she calls contexts, or spatiotemporal nodes inhabited by configurations of individuals and entities, constrain pronoun interpretation. Information about contexts attaches itself to mental representations that Emmott terms *contextual frames*. An action performed by (or on) a given configuration of participants is necessarily indexed to a particular context and must be viewed within that context, even if the context is never fully reactivated (after its initial mention) linguistically. Finally, Palmer (2004) studies how readers' world-knowledge allows them to make sense of a variety of techniques for representing fictional characters' minds. Synthesizing work on knowledge representations with accounts of the 'social mind in action' that are emerging in social psychology, philosophy, and linguistics, Palmer explores how readers construct inferences about fictional minds by using various textual indicators, including thought reports, speech representations, and descriptions of behaviors that span the continuum linking mental with physical actions.

Cognitive Linguistics and Cognitive Grammar: Regrounding CNA

In their overview of the field, Croft and Cruse (2004) identify three basic hypotheses underlying cognitive-linguistic research, namely:

i. language is not an autonomous cognitive faculty
ii. grammar is conceptualization
iii. knowledge of language emerges from language use

Further developed in the specific approach to cognitive linguistics that has come to be called *cognitive grammar* (Langacker, 1987, 1999), each of these hypotheses has important implications for CNA. Indeed, as confirmed by the publication of Stockwell's (2002) introductory textbook on cognitive poetics and by the interpretive applications gathered in Gavins and Steen's (2003) companion volume, ideas developed under the auspices of cognitive linguistics generally and cognitive grammar specifically have proven to be one of the must fertile sources of recent work in CNA (see also Semino and Culpeper, 2002).

Hypothesis (i) connects language use to other cognitive tasks, militating against generative grammarians' assumption of a special-purpose language faculty. From this perspective, psychological models of attention and perception (e.g. Gestalt theories of figure and ground) and theories of categorization processes involving prototypicality and graded centrality can be brought to bear on linguistic (and by extension narrative) phenomena. Hypothesis (ii) suggests that meaning cannot be reduced to language's truth-conditional correspondence with the world, and that semantic theories must therefore take into account the way the mind conceptualizes humans' embodied experience. Hence, the cognitive-linguistic focus on conceptual metaphors and image-schematic reasoning; this work suggests that source concepts deriving from having or rather being a body in the world are used to help construe novel experiential domains. Metaphors anchored in a positive valorization of being upright provide coordinates for making sense of emotions and attitudes (*I feel really up today* versus *I feel really low today*), as do image schemata deriving from what Talmy (1988) characterized in terms of 'force dynamics' (*I resisted the temptation, fighting against it with all my might*). According to hypothesis (iii), categories and structures at all levels of language organization are built up through inductive

schematization from specific utterances in specific contexts, in effect making discourse the birthplace of linguistic and for that matter meta-linguistic knowledge.

Practitioners within CNA have made productive use of many of these ideas. Particularly consequential in the recent development of CNA is Fludernik's (1996) account of experientiality as constitutive of narrative; her study harmonizes with work based on both hypotheses (i) and (ii). For Fludernik, unless the representation of an event-sequence conveys a sense of how those events were experienced by an embodied human or at least anthropomorphic consciousness attempting to construe them, then the representation at issue cannot be characterized as a full-fledged narrative. For his part, Turner (1996) draws on cognitive-linguistic research to develop the idea of 'parabolic projection,' which involves the use of a familiar source story to make sense of a less familiar experience, or target 'story.' Thus, allegories such as Euripides's *Alcestis* cast Death as an agent and thereby ascribe agentivity as well as intentionality to what would otherwise be an agentless happening, in the process transforming an atelic event into a goal-directed action. Providing further support for hypotheses (i) and (ii), projections of this kind suggest that narrative relies as crucially on image-schematic reasoning and conceptual metaphors as other kinds of language use. In recent work, the term *conceptual blending* (Fauconnier and Turner, 2002) has been used to describe how textual cues in narrative and other discourse create such laminated structures, blending states, objects, and events that would otherwise remain anchored in different conceptual domains. (Hypothesis [iii], it might be mentioned in passing, squares with Turner's 1996 argument that language is a product, not the cause, of humans' storytelling impulse.)

CNA also has drawn on developments in cognitive grammar, a subdomain of cognitive linguistics. A key idea of cognitive grammar (and one interconnected with all three hypotheses above) is that a basic psychological resource used to make sense of experience, namely, the contrast between figure and ground, constitutes a core cognitive primitive that manifests itself in the structures of language as well. Thus, the English word *aunt* means what it does because of the way it profiles a particular substructure of a larger conceptual base – namely, a specific understanding of kinship relations (Langacker, 1999: 27). Similarly, some linguistic expressions acquire their meaning by profiling a trajector as a primary figure that stands out against the secondary figure (or ground) of the landmark (if one is present) (Langacker, 1999: 31–32). For example, although *The cat is above the desk* and *The desk is below the cat* refer to the same spatial configuration of objects, the meaning of these two expressions differs. In a cognitive-grammatical account, the difference derives from contrasting conceptual structures involved: in one case the cat is profiled as a trajector against the desk as landmark, whereas in the other case the desk is the trajector and the cat is the landmark.

The previous examples concerned words and clauses, but practitioners of CNA have demonstrated that there are also significant discourse-level implications of these ideas from cognitive grammar. Stockwell (2002: 13–25), for example, comments on the the relevance of trajector-landmark profiling in a (quasi-)narrative poem by Ted Hughes, anchoring his discussion in a more general discussion of figures and grounds in the processing of literary texts. Similarly, Herman (2002: 263–299) has drawn on figure-ground relationships to explore processes of spatial reference in narrative discourse. Emmott (1997) has also discussed foreground-background relationships as a key component of contextual frames, e.g., when readers compute inferences about which characters are focal participants in a scene as opposed to the participants who form part of the background for the main action.

Contextualism (II): CNA after the Second Cognitive Revolution

In Harré's (1992) and Harré and Gillett's (1994) account, the first cognitive revolution marked a shift away from behaviorism to the study of cognition, postulating that "there are mental processes 'behind' what people say and do, that these processes are to be classified as 'information processing,' and that the best model for the cognitively active human being is the computer when it is running a program" (Harré, 1992: 5; cf. Harré and Gillett, 1994: 1–17). In contrast, although the second cognitive revolution also accepts that there are cognitive processes, it views them as immanent in discursive practices. People thus acquire the status of psychological beings just by participating in discourse, in normatively accountable ways (Harré, 1992: 6; cf. Harré and Gillett, 1994: 18–36). This second revolution, also referred to as discursive psychology (Harré and Gillett, 1994), began to unfold in the late 1980s and emanated from sources such as the later Wittgenstein's emphasis on meaning as use, Vygotsky's (1978) hypothesis that intramental functioning derives from prior experiences of intermental functioning, or shared thinking, and social-constructionist accounts of human identity. Although it builds on the first-wave contextualism discussed previously, discursive psychology seeks to radicalize the insights of earlier studies. Thus, Harré and Gillett (1994: 30–31) argue that Newton's

ontology of the physical world needs to be complemented with a Vygotskyean ontology of the social world, whereby an array of persons constitutes a system of location like Newtonian space and speech acts are the counterpart to 'things' in the Newtonian system (cf. Harré and van Langenhove, 1991: 393–394).

This paradigm shift has major implications for CNA – implications yet to be fully worked out, particularly for story analysts concerned with literary narrative. A key issue is the exact status of narrative itself in discursive-psychological research. The concept of narrative or 'story-line' is a basic analytic construct in the theory of positioning (outlined in, e.g., Harré and van Langenhove, 1991) that has influenced much of the research in this area. In Harré and van Langenhove's (1991) account, one can position oneself or be positioned in discourse as powerful or powerless, assertive or timid, etc. In turn, a position can be specified by characterizing how a speaker's contributions are taken as bearing on these and other 'polarities of character' (1991: 396) in the context of an overarching story-line being jointly elaborated by participants, via self-positioning and other-positioning speech acts.

But if the story-line is used as a basic explanatory device, a way of accounting for people's sense-making strategies in everyday social life, the question remains how narratively organized discourse practices bear on such overarching stories of self and other. What is the relation between (culturally or subculturally transmitted) story-lines viewed as global sense-making strategies and the cognitive activity involved in the moment-by-moment interpretation of particular stories in context? Furthermore, how might positioning in particular and the framework of discursive psychology more generally be extended beyond the study of communicative practices in face-to-face interaction and used to study stories conveyed in literary, cinematic, or computer-mediated formats? Can communicative encounters represented in literary fiction be construed as meta-positioning acts, whereby everyday positioning practices are held up for inspection, connected to new story-lines, and thereby denaturalized? Beyond fictional representations of positioning acts, in what ways might the structures of literary narratives – e.g., their use of embedded storytelling scenarios – be related to discursive-psychological research on the socially distributed nature of intelligence itself?

Prospects for CNA

Whereas my discussion has thus far assumed the basic viability of CNA as a framework for study, criticisms by Sternberg (2003) question both the extent to which CNA constitutes a genuine interdiscipline and the degree to which it enables true methodological convergence between fields concerned with narrative. Sternberg's (2003) wide-ranging critique mainly concerns the use of cognitivist methods for the study of literary narrative. Sternberg disputes that there has been any real rapprochement in this area, arguing that when it comes to the analysis of literary discourse in particular, linguists have not yet matched the most accomplished analyses advanced in the fields of poetics and criticism. Conversely, cognitively oriented theories of literary narrative tend to have more in common with one another than with the source disciplines from which they borrow. Part of the problem lies in the attempt to translate foundational concepts such as 'frames' and 'scripts,' 'emotion,' and even 'narrative' across what remains for Sternberg a disciplinary divide between humanistic and social-scientific research.

At the very least, Sternberg's critique reveals the extent to which CNA remains an unfinished project. If CNA is to become a bonafide interdiscipline, it will have to work toward synergistically combining its source concepts and methods into a whole greater – more capable of description and explanation – than the sum of its parts. Although not presuming to be exhaustive, the following is a checklist of concerns that will need to be addressed collaboratively by theorists working in different areas of the field if CNA is to move toward the goal of genuine interdisciplinarity.

Methodological Issues

- *Synthesis of quantitative and qualitative approaches*. Researchers in cognitive and social psychology, corpus linguistics, and other fields within the social sciences have developed methods for gathering, sorting, counting, and analyzing empirical data pertaining to stories. These quantitative (= 'empirical' or 'data-driven') methods address questions about *how much* (the degree to which) and *how often* (the frequency with which) those data display a given property or set of properties. By contrast, grounded in what might be called the phenomenology of reading, qualitative (= 'phephenomenological' or 'intuition-driven') methods address questions about *how* and *why* narrative data have the particular character that they do (Johnstone, 2000). CNA spans both of these research methods, and though some analysts have worked toward reconciliation and synthesis (van Peer and Chatman, 2001), much more needs to be done to increase dialogue among theorists working within these two broad perspectives.

- *Integration of research on narrative as target of cognitive activity with research on stories as mode of cognition.* To some extent, this divide parallels the other methodological split just described, since quantitative methods often are used to study narrative processing and qualitative methods are brought to bear on narrative viewed as a cognitive instrument. But in any case, CNA can only benefit from more dialogue among scholars who attempt, in these two ways, to connect narrative structures with modes of intelligent activity.

Topics Requiring Collaborative Research

- *Emotion.* Both Sternberg (2003) and Stockwell (2002) identify emotion as an underexplored area within literary CNA in particular (but see, e.g., Harré and Gillett, 1994: 144–161; Hogan, 2003). More generally, theorists in all areas of CNA need to pool their resources to investigate which explanatory frameworks can best account for the functions of emotion, viewed both as part of narrative content and as an aspect of the interpretation of stories.
- *Theory of mind/folk psychology.* Palmer (2004) and Zunshine (2003) suggest that narrative understanding hinges on interpreters' capacity to develop a theory of mind powerful enough to account for characters' beliefs, desires, intentions, and behaviors. In turn, practitioners of CNA need to collaborate in studying how people use stories to build a theory of mind in the first place. At issue is the way narrative provides a resource for folk psychology, generating meta-knowledge about human knowledge.
- *Narrative acquisition and narrative disorders.* Further study of the processes of narrative acquisition and of various sorts of narrative disorders (e.g., those deriving from schizophrenia, Alzheimer's disease, or traumatic injury) promises to throw light on the cognitive abilities bound up with 'narrative competence.' A cross-disciplinary perspective on these issues is most likely to pinpoint what constitutes competence (or its diminishment) to begin with.
- *Intermedial inquiry.* Intermedial research also may illuminate cognitive dimensions of narrative. Connecting scholars in the fields that inform CNA (linguistics, film studies, literary studies, etc.), research on narrative across media stands to reveal core aspects of narrative understanding as well as the extent to which narrative artifacts are translatable across various semiotic formats. A focal point for dialogue and debate is the question of whether the new electronic media reveal the power of narrative as a sense-making strategy, or rather expose its limits.

Narrative: Linguistic and Structural Theories

M Toolan, University of Birmingham, Birmingham, UK

Introduction

The production, reception, and use of narratives is one of the hallmarks of human life. Indeed narrative has been called a metacode and a human universal, with story-making now as widely bruited as metaphor as a basic mode of humanistic sense-making. As representations of events removed from the immediate here-and-now, narratives are a vital human resource in making sense of the world – and even in the making (construal) of that world itself. Indeed, some now suggest that it is the narrativizing faculty (with its other-orientedness or intersubjectivity and attention to goals and intentions), rather than simply a language faculty, that most sharply differentiates humans from other animals. Narratives reflect one of the key design features of the language faculty – displacement – although narrative is itself a faculty that can be realized in other media than the verbal. Narratives are also astonishingly various and heterogeneous in forms and functions, with rich possibilities for embedding of stories within stories.

In this article the focus is on contributions to the understanding of core elements of narrative that have come from narratologists and narrative poeticians, who chiefly consider fiction and film narratives; other analyses and models of narrative – e.g., those rooted in sociolinguistics, anthropological linguistics, ethnomethodology, and elsewhere – are addressed in a range of separate entries. One important development not addressed here because it is treated fully in a

Narrative: Linguistic and Structural Theories

M Toolan, University of Birmingham, Birmingham, UK

Introduction

The production, reception, and use of narratives is one of the hallmarks of human life. Indeed narrative has been called a metacode and a human universal, with story-making now as widely bruited as metaphor as a basic mode of humanistic sense-making. As representations of events removed from the immediate here-and-now, narratives are a vital human resource in making sense of the world – and even in the making (construal) of that world itself. Indeed, some now suggest that it is the narrativizing faculty (with its other-orientedness or intersubjectivity and attention to goals and intentions), rather than simply a language faculty, that most sharply differentiates humans from other animals. Narratives reflect one of the key design features of the language faculty – displacement – although narrative is itself a faculty that can be realized in other media than the verbal. Narratives are also astonishingly various and heterogeneous in forms and functions, with rich possibilities for embedding of stories within stories.

In this article the focus is on contributions to the understanding of core elements of narrative that have come from narratologists and narrative poeticians, who chiefly consider fiction and film narratives; other analyses and models of narrative – e.g., those rooted in sociolinguistics, anthropological linguistics, ethnomethodology, and elsewhere – are addressed in a range of separate entries. One important development not addressed here because it is treated fully in a

separate article concerns the putative genderedness of narratives, narrative production, and reading (*see* **Narratology, Feminist**).

Core Elements: Story and Discourse

It may not be possible to offer here a wholly satisfactory definition of narrative, because the theories to be discussed have in fact objects of enquiry that differ from each other in significant respects. Nevertheless a minimal characterization may be proposed:

> a perceived sequence of nonrandomly connected events, i.e., of described states or conditions which undergo change (into some different states or conditions).

By 'nonrandom connection' is meant some connectedness that is taken to be motivated and significant. This principle is formulated in terms of "transformation" by the structuralist Todorov (1977: 233):

> The simple relation of successive facts does not constitute a narrative: these facts must be organized, which is to say, ultimately, that they must have elements in common. But if all the elements are in common, there is no longer a narrative, for there is no longer anything to recount. Now, transformation represents precisely a synthesis of differences and resemblance; it links two facts without their being able to be identified.

But perceiving nonrandom connectedness in a sequence of events is the prerogative of the addressee: the ultimate authority for ratifying a text as a narrative rests not with the teller but with the perceiver/addressee. Before structuralists and literary theorists and sociolinguists turned to narrative, however, it had been examined with considerable analytical sophistication by folklorists and anthropologists, tending to identify as narratives those stories where an initial state of equilibrium is disturbed by various forces of turbulence, before some sort of action (perhaps a magical intervention) leads to the restoration of a modified version of the original equilibrium.

Recent studies in narrative poetics have tended to divide the subject of study into two main domains or levels of inquiry. Thus, the early 20th-century Russian Formalists (Propp, Tomashevsky, etc.) distinguished *fabula* from *sjuzhet,* roughly equivalent to the more recent French (*see* **Benveniste, Emile (1902–1976); Barthes, Roland (1915–1980)**) terms *histoire* and *discours*. These are equivalent in turn to the widely adopted English labels (as in Chatman, 1978) of story and discourse. By the first term of each of these pairs is meant a basic description of the fundamental events of a story, in their natural chronological order, with an accompanying and equally skeletal inventory of the roles of the characters in the story:

> A fabula is a series of logically and chronologically related events that are caused or experienced by actors (Bal, 1985: 5).

This is the level at which we may expect the possibility (and impression) of 'total transfer' from one medium to another: everything at the level of story in, e.g., Dickens's *Great Expectations* can and perhaps should appear as easily in a film or cartoon version, or a ballet, as in the original written version. In a story outline all the events and characters are presented synoptically, with the minimum attention to, for example, complexities of sequence – it as if the paradigmatic raw materials of the narrative are displayed. The syntagmatic dimension, the linear distribution of event-and-character presentation, disclosure, elaboration, and so on, is severely attenuated.

Relatedly, the *sjuzhet* or *discours* of a narrative is the version of the core story that is realized in an actual cinematic or dance or literary creation. In fact both the process and the product – the realizing and the realized end product – are referred to by these terms. For *sjuzhet* and *discours* also denote all the techniques that authors bring to bear in their varying manners of presentation of the basic story.

In literary studies, discourse has been viewed as the more interesting area of narrative poetics, whereas story has been treated as a focusing on the preartistic, genre- and convention-bound basic event-and-character patterns of narrative, with scarcely any room for evaluative contrasts or discriminations, a level at which authorship seems an irrelevant concern. It is worth stressing that such a marginalizing of story is controversial in some quarters, where attention has been directed to the cultural and ideological 'work' done by certain kinds of recurrent story elements, character-types, generic plots, and so on. Despite such revaluations, this pair of terms remains current, with discourse understood as the artistic and individualized working with and around the genres, the conventions, the basic story patterns, in the distinctive styles, voices, or manners of different authors.

Events and Event-Structure

Propp's Morphology

The starting-point of Propp's famous study (Propp, 1968, originally published in Russian in 1928; *see* **Propp, Vladimir Iakovlevich (1895–1970)**) seems to have been something like the minimalist definition of narrative introduced earlier – a text in which there is recounted a change from one state to a modified state, i.e., an event. In his proposed 'morphology' of the Russian fairy tale, Propp offered an inventory of all

and only the fundamental events (called 'functions') in his chosen corpus of 115 Russian fairy tales. Looking particularly for recurring elements or features (constants) and random or unpredictable ones (variables), Propp concluded that although the characters or personages of the tales might superficially be quite variable, yet their functions in the tales, viewed in terms of the story's development, were relatively constant and predictable. Both the number (31 in all) and the sequencing of the functions is asserted to be fixed. Examples from the set of 31 functions include

1. One of the members of a family absents himself from home. (An extreme exponent of this function is the death of one of the parents.)
2. An interdiction is addressed to the hero.
3. The interdiction is violated.
16. The hero and villain join in direct combat.
31. The hero is married and ascends the throne.

Propp noted some internal patterning within the 31-function sequence. Certain functions clearly go together as pairs, such as prohibition and violation (2 and 3), struggle and victory (16 and 18), and pursuit and deliverance (21 and 22). Clusters of functions are also grouped under general headings. Thus, functions 1–7 are potential realizations of the 'preparation,' 8–10 are the 'complication,' and later general groupings include 'transference,' 'struggle,' 'return,' and 'recognition.' In addition to the 31 functions Propp identified 7 basic character types or roles:

villain; donor/provider; helper; princess (+ father); dispatcher; hero (seeker or victim); and false hero.

An actual character may fill more than one character-role (e.g., some individual in the tale may be both villain and false hero) and of course one role might be filled by several individuals (there might be several people jointly functioning as helper or villain).

Propp's methods have been used extensively, particularly in anthropological studies, and it is certainly striking that fictions rather remote from the Russian fairy tale (children's stories, TV crime series, etc.) do seem to lend themselves to Proppian analysis. But at the same time the question of reductivism has persistently undercut regard for Propp's work – particularly when attempts are made to apply it beyond the fairy tale. It is argued that the morphology is a model that severely distorts, because it sets on one side the important and necessary cultural context in which these tales occur and ignores also the varying details of stories. The counterargument is that a structuralist–morphological approach must necessarily 'reduce,' and explicitly sets out to shear off the nonessential from the essential, appealing to intuition. Truly uncovering intuitive judgments (rather than learned and conditioned ways of talking publicly about plots and plot structures) will always present difficulties. But the substantial degree of agreement that similarly acculturated groups of readers reveal, concerning what they regard as essential or not in plot and character and in other respects, suggests that some common sense of structure exists. Like all other kinds of common sense, this is undoubtedly relative to sociocultural determinants and ideologically motivated in subtle ways. But this generality of agreement and commonality of sense are the essential justification for the inductive speculations of Propp, Barthes, Todorov, and others (*see also* **Barthes, Roland (1915–1980); Structure and Structuralism: Semiotic Approaches**).

Barthes's 'Functions'

Barthes (1977 [1966]) proposed three major levels of narrative structure:

a. functions (as in Propp and Bremond);
b. actions (roughly, characters – cf. Greimas's *actants*, discussed later),
c. narration (equivalent to the *discours* or discourse described in the first section).

In fact Barthes focused almost entirely on the level of functions or narrative events, the level at which narrative is 'driven.' Every function has the effect of starting or developing a story line that will have consequences at a later point in the narrative; thus function is teleological. It is the means of achieving the overarching coherence of a narrative, rather than any merely local or proximate cause-and-effect logic. There are for Barthes two types of functions: functions proper (similar to Propp's) and indices. The latter include pointers to characters' psychological states, notations of atmosphere, and so on. Whereas functions proper are distributional, sequential, 'completed' further on in the story, and so have a kind of syntagmatic rationale and ratification, indices are said to be integrational, hierarchically oriented, empowered by the reader's relating of them to some higher, integrated level, a paradigmatic ratification. On a broad continuum, Barthes suggests, there are heavily functional narratives such as folktales, in contrast with heavily indexical ones such as psychological novels.

Barthes subcategorized both functions and indices. Thus, the former are of two types, nuclei (cardinal functions) and catalyzers. Nuclei are moments of risk, hinge-points or branches in story development, where events could proceed in two radically different directions; they are consecutive and consequential. Catalyzers 'fill in' between nuclei and are parasitic on

them; they are the prevarications and other accompanying actions that may flank a genuinely nuclear function. Indices can also be ranked for salience, with indices proper, charged with implicit relevance in, e.g., character portrayal, contrasted with informants, which are relatively insignificant and depthless identifiers. Furthermore, a unit can be a member of more than one class at time: it could be both a catalyzer and an index, for example. But nuclei (also termed kernels) remain the core items providing the necessary framework, the other three types being enhancements of these.

Even the smallest of these segments may combine into coherent sequences (in a way reminiscent of Propp's notion of clustering, and of phrasal syntax generally):

> A sequence is a logical succession of nuclei bound together by a relation of solidarity: the sequence opens when one of its terms has no solitary antecedent and closes when another of its terms has no consequent (Propp, 1968: 10).

For example, 'having a drink' is suggested as a closed sequence with the following nuclei: order a drink, obtain it, drink it, pay for it. Seeing a sequence in such a string of reported events, and labeling it as 'having a drink' is for Barthes the kind of projective interpretive activity readers are always performing in their narrative processing (this is later subsumed under the proaieretic code: see Barthes, 1970). Naming is the key act of mental processing, under the assumption that the reader is selective in attention in the course of reading or hearing a narrative and instead registers, and may even verbalize, the main threads of the narrative. The reader enacts an incremental and revisable précis making.

Despite the attractions of Barthes's basic four-way categorization of narrative material, problems immediately arose and persist concerning reliability of identification of nuclei, informants, and so on – i.e., concerning diversity of interpretation. It may be concluded that kernels and catalyzers are less textual givens than analytical constructions, and that, in true Saussurean structuralist terms, they are essentially relational units:

> What is a kernel in one plot or at one level of description will be a satellite [catalyzer] at another. For the hero to lie in wait for the villain is, at one level, a kernel, since it logically requires a temporal consequence: the villain arrives and is shot down. But at another level these functions are satellites which expand the kernel 'revenge,' the consequence of an initial kernel such as 'suffering harm' (Culler, 1975: 13).

In readers' retrospective processes of sense-making and plot-determination, Barthes's notion of sequence-identification, or something similar, must be crucially involved. But much of this model-building is guided by our cultural background and our assumptions about 'normal' behavior. It is because there is always this context of cultural significances and saliences 'around' all our involvements with narratives that Barthes says we have 'a language of plot' within us even before we approach any particular story (*see also* **Barthes, Roland (1915–1980)**).

In the last dozen years or so, many narratologists and discourse linguists have revisited such fundamental notions as event and 'eventhood,' the episode, narrativity, and the bases on which a causal and not merely sequential relation is inferred between events. In a plot-based approach to narrative those are clearly the fundamental building blocks of production and comprehension, but their linguistic shape and grammaticization (e.g., via contextually contrastive use of tense, aspect) or reflection in particular lexical choices, defy easy formulation.

Plot-intuitions and Summaries, and Grammaticization

In addition and perhaps in contrast with the assumption that his morphology uncovers the essential structure of a corpus of stories, Propp's work may be seen as an exploitation or display of (Russian fairy tale) readers' narrative competence, i.e., of the kinds of structuring and progression that story-recipients apparently expect and require in particular kinds of tales. This reader-oriented emphasis is the basis for research on sharedness of plot-identification and evaluation, ability to summarize plots and agreement on what constitutes a good summary, and agreement in recognition of the transformational relatedness of plots. Culler (1975) argued that evaluation of models of plot analysis must be in terms of the adequacy as models of aspects of readers' 'literary competence' (here, intuitive knowledge of plot essentials, plot similarities, etc.). But literary competence significantly contrasts with what is claimed of 'linguistic competence' in generativist theory, because the former is learned and markedly culture specific.

Relatedly, calling these culture-specific abilities 'intuitive knowledge' remains a matter of debate (significantly, in areas such as discourse analysis, in recent years, the emphasis on intuition has been displaced to some degree by one on shared knowledge, or common background). People can be better or worse at plot summarizing and can improve at

it. In Western societies, constructing and communicating plot summaries is a valued skill; it might not be so in a settled oral community, where a set time and social space was reserved for storytelling. There, to précis a plot might be either incomprehensible or taken as indicative of poor storytelling skills. In addition, literary texts are arguably a problematic testing ground for general principles of summarizing, such narratives being too category-marginal, too deautomatizing of plot logic, to be suitable exemplification of our standard ability to summarize. The case of literary fiction is perhaps particularly expressive of Henry James's famous rhetorical questions and their challenge to the structuralist assumption of the separability of event, character, and setting:

> What is character but the determination of incident? What is incident but the illustration of character?

At a more narrowly grammatical level, interest continues in the possibilities of specifying the typical grammatical features of, for example, fully narrative or functional clauses (and, by contrast, of nonnarrative clauses of description, evaluation, and background). Various functionalist-oriented linguists support the postulation of a set of lexicogrammatical features that may be most expected and salient in narrative clauses. Additionally, there may be a need to rank, from most expected or appropriate to least so, the range of options that are possible candidates at particular points in text structure. Thus, past tense transitive clauses of action, physical or mental, may be one kind of most expected clause in narratives (cf. the narrative clause *Goldilocks ate up all the porridge* with the more descriptive clause *Goldilocks was hungry*). Similarly there seem to be narrative–clause preferences for nonprogressive aspect (*ate* not *was eating*); *realis* rather than *irrealis* mode and positive polarity rather than negative (thus not *would (not) have eaten*); and a clearly individualized participant as subject and actor (not *the porridge had been eaten*). Some such set of preferred options in the grammar of narrative clauses may in turn guide a reader's real-time processing of text in the search for plot, constituting links between grammar and plot structure. But such lexicogrammatical tendencies are preferences or expectations, not stipulations hence are provisional and liable to be overridden in particular narrative situations. They and the provisional plot assessments they give rise to may need radical recasting as the reading process is enacted and completed.

Temporal Order, Duration, and Frequency

This section concerns the temporal aspects of the transformation and elaboration of a story as a discourse (as those terms were characterized earlier). A starting point must be acknowledgment of the heavily convention-laden nature of so-called story time and text time: in both cases a verbal representation of temporality, rather than actual temporal progression, is the focus of study. And the processes of time representation are made more richly complex by the fact that the performance of narrative reception – listening to an oral story, or reading a written one – itself involves some passage of time. Artifice and aesthetic issues are therefore involved here, where the reader/analyst may be postulating or assuming some kind of match between real-world temporality as this is implied in the story and our sense of time passing during the experience of processing the narrative discourse. Another kind of disruption of a steady linearity of the temporal dimension of narrative is entailed whenever a narrative involves more than one story line, i.e., more than one set of developing circumstances affecting at least partially distinct sets of characters. But even where the correlation between real-world time and text-world time seems least noticeable or manipulated as in pure direct speech storytelling (monologue or dialogue), it is probable that the actual extent of the reading time considerably exceeds that which would be spent in an actual enactment.

The most influential recent theorist of text time has been Gérard Genette (1980, 1988), who specified three chief dimensions of temporal articulation of story in discourse – order, frequency and duration – addressed in the following:

a. Order: the relations between the assumed sequence of events in the story and their actual order of presentation in the narrative. Any storytelling departure from the natural or logical order of events is an anachrony, these being achronological movements either back in time (a delayed disclosure of an earlier-occurring event, or flashback) or forward in time (a premature disclosure of a later-occurring event, or flashforward). Genette's terms for these anachronies are analepsis and prolepsis, respectively. An analepsis, further, may take the reader back to a time earlier than that which has previously been established as the starting point of the story, in which case the analepsis is termed 'external'; or the shift may be to an earlier time within the established frame: an 'internal'

analepsis. Both kinds of temporal jump may be either 'homodiegetic' or 'heterodiegetic,' i.e., relating events involving the same character or story line as was the focus of attention immediately before the textual shift (homodiegesis) or relating events involving some other character or story line than the one previously focused on (heterodiegesis). And more complex narratives, such as Genette's chosen study, Proust's *A la recherche du temps perdu*, show that there are ample opportunities for analepsis within analepsis, heterodiegesis within homodiegesis, and so on, and the functions of such anachronies are equally numerous. A caveat worth recording immediately concerns the need to distinguish fleeting anachronistic allusions to temporally distant events (e.g., in the course of character portrayal), from substantial shifts of temporal grounding, anachronies proper. The former may be better thought of as analeptic or proleptic traces, contributions to a rich narrative texture (in Barthes's terms, indices or informants rather than functions).

b. Frequency: the congruence, and means of divergence, between frequency of some event happening in the story, and frequency of its narration in the text. Modernist novels, such as Faulkner's, often reveal interesting manipulations of frequency, away from the singulative norm (telling once what happened once). Thus, Faulkner's *Absalom, Absalom!* focuses on the murder of Charles Bon, told 39 times in all, by various tellers; whereas *As I Lay Dying* involves multiple tellings of the death and burial of Addie Bundren, and *The Sound and the Fury* includes versions of particular events (from Benjy, Quentin, Jason, and a more detached narrator) from significantly contrastive perspectives.

c. Duration: for Genette, this covers the relations between putative temporal extent of events in the imagined world of the story, and the textual extent of treatment in the narrative: duration is both the most problematic and the most creative of dimensions of temporal formulation. Genette's interest is in narrative pacing as a text–internal strategy, rather than in relating it to external factors such as duration of reading time. Thus, textual pace at any point in a narrative is to be assessed relative to pace (protractedness or brevity of event narration) elsewhere in the same narrative. Thus, for every narrative, norm of pace can be derived, against which notional departures can be charted. Constancy of pace would emerge if the ratio between story duration and extent of textual presentation were invariant – e.g., a chapter for every year of a character's life, with a page for every month of each year. The weaknesses in this approach lies in its mechanical and simplistic treatment of what is rarely so simple a textual phenomenon – notations of time elapsed, in a story, may be scarce and ambiguous – and its failure to concentrate specifically on the sense of rapidity of disclosure that readers report experiencing in their reading of particular delimited scenes. The latter phenomenon, perceptions of local accelerated telling, may again be related to lexicogrammatical features, such as use of transitive clauses, many different clause themes and affected participants, and nonfinite progressive clauses.

It seems possible and reasonable to distinguish duration from narrative selectivity and discontinuity. The latter concern the various blocks of time that a reader infers must have elapsed between narrated events and ordinarily will have no special interest: e.g., where a character retires to sleep at the end of one chapter and is depicted taking breakfast the next morning at the opening of the following chapter. Duration and variations of duration are not concerned with narrative gaps of this order, but rather with variations of extent in telling, from the evidently protracted to the evidently neglected or suppressed, of those things that are indeed told.

The extremes of textual duration are ellipsis (no textual treatment of some temporal segment of the story) and descriptive pause (textual presentation of that which involves no passage of time in the story). But more widespread are relative accelerations and decelerations, commonly labeled 'summary' and 'scene.' Shift of duration from the summary to the scenic is typically taken as a narratorial indication of the importance of the events and conversations so presented, whereas a shift from the scenic to the summary will often be taken to signify that the reported events are of secondary or backgrounded importance. Consequently, shock and ironic effects can be achieved by textual inversion of such norms – fleeting depiction of some cataclysmic event, framed by lengthily described routine matters. A complication common in modern novels is the attribution of choices in textual duration to a character within the narrative, whose thoughts are being represented, rather than to an external narrator. Thus, within the single scene of Peter Walsh's morning visit to Clarissa Dalloway (in Woolf's *Mrs. Dalloway*) there are both scenic and summarized mental recollections, by Clarissa, of their encounters in the past. And this recollected material is part of a story of far greater time span (Clarissa's life) embedded within one of relative brevity (Clarissa's day). As a unit within the framing narrative the reminiscence maintains normal

order, apparently text–normal duration, and singulative frequency. But as a separate narrative embedded within the framing narrative, it is marked by various anachronies, with variations of duration (some recollected events are highly summarized) and some repetitive frequencies. Useful as such applications of Genettian order and duration may be, they seem not to address directly the reader's experience of the text, which is primarily linear, whatever the narratorial practices of temporal reordering and embedding. In complex ways that may resist analytical unraveling, readers may – and arguably have to – synthesize the story of things happening with that of happenings remembered. In such a holistic reading, Mrs. Dalloway's reminiscences may paradoxically be both timely as well as anachronistic, past in actuality, present in consciousness.

Character

Until recently, there was noticeable neglect of character by narratologists (but important recent contributions include books by Phelan, Culpeper, and M. Smith). Some of this neglect reflected ambivalence about the ontological status of characters or individuals in fictional narratives, itself a reaction to lay and literary critical tendencies to talk and write about fictional characters as if they were real people. By contrast structuralists saw character as mythical in the sense of involving fabrications and illusions to a powerful and compelling degree; for that very reason it was taken to be a core principle device of narrative, whereby addressees are drawn to assess and evaluate a story's actors by their own deepest-held standards (ethical, social, or aesthetic). The compelling illusion is one in which the reader is a creative accomplice: a variety of descriptions of some posited individual, together with descriptions – implicit or explicit – of that individual's actions and reactions, suffice to lead most readers to conceive of a person of whom these references and insights are just glimpses.

The strictly structuralist–semiotic view is that all character descriptions are notations, linked by nothing more psychological than textual devices asserting coreference (repetition of a name, of pronouns, and of definite descriptions), comprising a fabric of interwoven traces: message-bearing (semiotic) data on the status, goals, drives, consciousness, etc., of a person embedded in some particular culture, located in history, shot through with various (potentially inconsistent) values and beliefs, defined by their putative gender, class, ethnicity, and subtler affiliations. The text of the person, in narratives, belies individuality and at every point discloses typicality. This 'purist' approach to character asserts the nonrepresentational dimension in narrative art, treating Hamlet and Dorothea Brooke as textual entities (things), not people.

What is most apparent in this contrast of approaches to character, the individualizing approach (where the reader is 'seduced' into suspending their disbelief and apprehending the character as a person) versus the constructivist (where the reader remains resistant, detached, and judging of the narrator's efforts to represent characters), is that they counterpose quite different ways of reading, ways that adopt quite different criteria for reading narrative, and for the identification of great narrative, in the first place. (In part, too, the debate is related to a foundational one about naturalism versus conventionalism in semiotic systems, and the ontological status of representation.) A dual perspective is needed, where we see characters in a different light according to the change of perspective. Most readers continue to perceive characters (particularly in novels) as individuals (whether seen dimly or sharply, fathomable or alien), and as those perceptions are built up, revised, and articulated, all sorts of extratextual knowledge, including knowledge of characters in the everyday world, is brought to bear. The reverse is also true: our experiences of literary and film characters affecting our construction of ourselves and others. Such practices are consonant with a theorizing of fictional and nonfictional worlds that assumes that in both a semiotic constructedness of people, things, settings, and events operates, so that both the fictional and the nonfictional are representational to their roots.

Greimas's Actant Model

One attractively simple model of character-roles in narrative, a tellingly workable anatomy that has been adapted and applied in diverse fields, is that of Greimas (1966). He has proposed that, as general categories underlying all narratives, there are just six character roles, or *actants*, comprising three interrelated pairs: giver: receiver; subject: object; and helper: opponent. The six roles are usually diagrammatized as shown in Figure 1.

Such a model fits many traditional folk and fairy tales remarkably well: the subject or hero, perhaps a young man of lowly origin, seeks marriage to a beautiful princess (object), in which case the man will also be beneficiary (possibly the princess and the country will too). In his quest he is helped generously but with

Figure 1 Greimas's actant network.

limited success by a friend or relative (helper), but their combined efforts count for little, in the struggle against some opponent (a wicked uncle of the princess, some other eligible but ignoble suitor), until a sender (better, a superhelper) such as the king, or God, or some individual with magical powers for good, intervenes.

Despite the model's simplicity, and despite the need to annotate it variously so as to fit different genres better, the scheme is worth applying to a range of texts, from religious stories to Henry James's *The Ambassadors*. One thing to note is that two of the 'roles,' Sender and Object, are not typically strictly characters at all in most modern stories: modern literary narratives are likely to have quality of life, liberty or liberation, the pursuit of happiness, or greater self-knowledge, or mental peace, as their object. Nevertheless there remain plenty of spy stories, westerns, romances, and detective stories, however, where a particular concrete object is clearly the target. The role of higher help is interestingly problematic: in a secular and rationalist society, there is evidently some resistance to adult narratives that invoke such a role.

Greimas's six-role schema seems particularly applicable to advertisements, where the targeted consumer is understood to be both subject and receiver, the object is something contributory to a new or improved lifestyle, while the marketed product often functions as superhelper. In a range of product-oriented advertisements there is a narrative-style emphasis on change of state, and the product providing some important assistance in that transformation. However, this narrative format tends to fall away in the promotion of truly luxury items, such as perfumes, fur coats, very expensive cars, and so on. In these, a more synecdochic relation seems to obtain, where the product is presented as intrinsic part (however small) of the chic and elegant lifestyle that the advert typically portrays. The product is part of the object, rather than representing the sender.

Character Traits and Distinctive Feature Analysis

In many modern narratives of the more complex kind, details of characterization – the kind of material that Barthes labels as indices or (mere) informants, often irrelevant to story – are just what the reader finds most engrossing. In evaluating such material, readers are inevitably guided by real-world background knowledge, the mental scripts and schema that we bring to our reading of any narrative, derived from our previous experiences of individuals, events, and situations. Such knowledge has been characterized as an interwoven complex of facts and ideology. Some of this knowledge is perhaps particularly important, as it can underpin a kind of feature analysis of the characters.

A semantic feature analysis (loosely analogous to distinctive feature phonology) of the characters of a tale involves specifying a limited list of what the analyst takes to be the crucial and contrasting attributes that distinguish particular characters. From this viewpoint, extensive description of character is secondary and even undesirable (just as, in the similar phonological analysis, the minimum set of contrasts needed is the preferred set). Although comparison and contrast of characters in terms of attributes is basic, a refinement of the method involves assessing variations in degree (how weakly or strongly?) and modality (how probably or usually?) of an attribute. And in light of the importance of change to narrative, a further enrichment is where a character's shift in 'trait realization,' e.g., from being proud and presumptuous to being chastened and grateful, can be recorded. Given the nature of narratives and their reception, the method does not assume the same level of agreement in analysis, powers of prediction, and replication, as are claimed for distinctive feature analyses in phonology or semantics. Rarely will reader analysts agree over the precise set of features appropriately present or absent in a text's characters. Such variant emphases, in analyses, are in themselves and in their reflection of analysts' assumptions an indication of ideological and interpretive diversity. The feature matrices that this method nurtures are often held in low esteem today, yet a great many critical commentaries on literary narratives draw, in their discussion of character motivation and appropriateness of plot development, on informal accounts of characters' crucial traits. A more difficult charge to refute is that the model takes reductive structuralism to an extreme, so that the given texture of characters, their syntagmatic extension through a long narrative, is largely neglected.

Names and Faces

Names and faces are so typically attributes of individuals that are immediately in the public domain, and so often regarded as unique and indicative, that they are a staple resource for characterization. In matters of naming, textual designation of a character by way of proper name, or definite descriptions, or pronominally, is a basic choice that often reflects narratorial point of view. The effects of irony or sympathy, approval or distaste achieved by particular naming strategies can be quite complex, given that there is usually an ongoing designating of several characters, in any stretch of text, by these varied means.

Another heavily exploited means of characterization, often with the assumption that outer surfaces

reflect inner essence, is description of characters' outward appearance – especially clothes and facial features. Given the rarity of surgical adjustments of the latter, one commonsense rational assumption is that looks, build, and physical qualities of an individual (and so, a character) are both given and arbitrary, certainly rejecting any claimed causal link between appearance and personality (such theories of physiognomy and phrenology, popular in the 19th century, influenced writers such as Balzac and Dickens). On the other hand, common sense also recognizes the multiple consequences, in life, that particular physical attributes can assist or impede. Physical attributes are in this sense facts in the world, constraining and defining individuals in very real ways (sex, skin color, and physical handicap being three of the most socially defining). Cyrano's protruding nose, Falstaff's vast belly, Esther Summerson's disfigurement by smallpox, and Othello's blackness are just a few instances where body, life, and narrative fate seem to interact. Then again, some features of physical appearance such as body shape, hairstyle, facial expression (propensity to frown, with head lowered, versus a smiling disposition with an 'enquiring' tilt of the head) are judged to be partly under a character's control, something for which they can be held accountable.

The source of character apperception that is perhaps most complex to chart – using structuralist or any other methods – is the process of implicit characterization based on how a character acts and reacts. Twentieth-century fiction has tended to opt for the indirectness of presentation, a 'showing' of character that respects the ability of the reader to infer, evaluate, and draw conclusions on the basis of presented behavior, rather than direct (and directive) presentation, an authoritative one, of how a character is. But the multiplicity of types and formal exponents of what Barthes first called indices and informants and later (in *S/Z)* assimilated to five overarching interpretive codes, seem triumphantly resistant to grammarlike modeling.

Characterization through Dialogue

One of the most striking things that characters do in literary narratives is speak and think, and the nature and structure of characters' reported discourse is treated in several independent entries (*see*, e.g., **Dialect Representations in Texts; Speech and Thought: Representation of**). But some evidence is also derived from *how* characters in narratives participate in conversation: how cooperatively, aggressively, sensitively, and so on, they interact. Models that have been widely applied in such analyses of fictional dialogue include the ethnomethodologically oriented tradition of conversation analysis (Sacks, Schegloff, etc.), the discourse analytical system associated with linguists at Birmingham University (exemplified by Burton, 1980), and more pragmatic and social psychological approaches that focus on how individuals' conversational contributions are shaped by concern to maintain an appropriate image of self and other, so that 'face,' 'politeness,' and other pragmatic principles are greatly affecting just how turns of talk are formulated (see especially Goffman 1981; Leech, 1983; Brown and Levinson, 1987). But probably the greatest influence has been wielded by Grice's seminal paper of 1975, in which his Cooperative Principle and its four subsidiary maxims of quality, quantity, manner and relation are outlined, together with his account of how addressees (including here, readers) derive implicatures concerning the speaker's covert or indirect meaning, where there seems to be a calculated departure from simple maxim observance.

Setting

Though less essential to a narrative than event and character, the establishment of an identifiable setting is a strong psychological preference in most readers. We like and expect clear spatiotemporal indications of just where and when a thing happened. However, this specificity requirement seems relative to genre and story type: some fables and folktales do not need elaborate details of setting, nor do certain speculative or psychological stories, whereas Kafkaesque or Beckettian stories may appear deliberately to withhold setting.

In the novel, settings (especially but not exclusively residential ones) are often depicted at length and come to seem inseparable from character and motivation: they may function like a character (at least a Forsterian flat one), and be the cause of various events. In novels by Fielding and Austen, particular houses, country estates, inns, parsonages, and cottages are instrumental in this way, as may be the contrast between a drawing room and an open-air encounter. In analyzing fiction from the late 19th century onward, critics have come to attend to questions of public and private space and gender, and changes in these, especially where implicit norms in these matters have functioned to confine women to their 'proper place.'

Although it is customary to talk of the relations between setting on the one hand and character and events on the other as either causal or analogical, often texts are indeterminate between these two types of relation. Hardy's characterizations of Egdon Heath in *The Return of the Native*, for example, are so distinctive and compelling partly because we sense

but cannot fathom the influences the heath has on specific characters. But even quite conventional and 'undramatized' settings play an important part in promoting verisimilitude and indirect characterization.

Narrators, Narration, and Focalization

A distinction in narratives may be made between:

a. the individual or position we judge to be the source and authority for whatever words are used in telling; and
b. the orientation we infer to be that from which what gets told is told.

The first of these factors is 'narration'; the latter, arguably only a highly developed aspect of the former, is known as 'focalization.'

Narrators and Narration

Just how many optional or obligatory roles are involved the process of narration remains richly controversial. Many narratologists (e.g., Chatman, 1978: 151) identify as many as six major participants (Figure 2).

In Chatman's discussion, the real author and reader are left out of discussion, on the grounds that their 'implied' counterparts are their functioning substitutes in the business of narrative transmission, and the further claim is made that the narrator–narratee pair are optional positions. Others, perhaps chiefly concerned that study of literary narratives should not appear unrecognizably different from more comprehensive study of narratives in society, have argued for just three essential roles in narrative transmission, and an optional fourth (e.g., Toolan, 2001) (Figure 3).

It is no accident that of the six roles usually discussed in narratological studies, these three are the ones that are robustly present on the surface of narrative texts and the most deeply recalled when we ordinarily think about narratives. By contrast, the implied author, the narratee, and the implied reader are rather more notional: potentially analytically important, but in more oblique ways.

The implied author is the mental picture of the author that a reader constructs on the basis of the text in its entirety. That such an imagining of the author can and often is undertaken is easiest to see where we read an unattributed text. More important than the general characteristics a reader might impute to the implied author are the values – the ideology – that, rightly or wrongly, the reader imputes to him or her. The reader reasons that in having constructed the kind of narrator to be found in the narrative and in having written about the kinds of things here written about, and written about in just the way found here, the implied author must tacitly subscribe to these particular values rather than others.

The notion of the 'implied author' was first proposed by Wayne Booth (1961), who suggested that each of an author's novels projects a different 'official version' of that author and his or her values. But such versions can be separated from the actuality of authorial narrative production: they may be important in narrative reception and critical theory, but are arguably irrelevant to narrative production. In this view, the 'implied author' is a real position in narrative processing, a receptor's construct; but it is not a real role in narrative transmission. It is a projection back from the decoding side, not a real projecting stage on the encoding side. That is to say, it is extremely doubtful whether writers do set out to create an implied or refracted version of themselves, perceptible by the reader, over and above (and logically prior to) the creation of a narratorial persona, in each of the fictions they embark upon. It is harder for most readers than Booth assumes, to keep in mind and separate an 'official scribe' and an 'official narrator.'

Although sociolinguistically oriented narratologists argue for a reduction of the production side of narrative transmission from three participants to two, they tend to simplify the reception side even further: they disregard two of the participant roles assumed in much narrative poetics (narratee and implied reader) and treat only the real socially situated reader as central. Again, this reduction involves no denial that narratee and implied reader are important strategic positions in the processes of narration and narrative reception (for vigorous defense of poeticians' enlarged view of the narratee, see especially Prince, 1983). The narratee is an individual, whether involved in or detached from the events of the story, who is directly addressed and to some degree characterized by the narrator (the process of characterizing an addressee is important: on this criterion, many first-person narratives of *prima facie* 'direct address' do not have an addressee: *Tom Jones* has such a narratee, *Great Expectations* does not). Very occasionally narrators address their discourse to themselves, but much more typically the addressee is a character–receiver within the story, even if one seemingly marginal to the action. Sometimes, as in Sterne's *Tristram Shandy*, a narratee

Real author → Implied author → (Narrator) → (Narratee) → Implied author → Real reader

Figure 2 Participants in the process of narration.

Author → Narrator → (Narratee) → Real reader

Figure 3 Core participants of narration.

is playfully conjured up and, for instance, castigated for inattentiveness. But in all such cases, with their overt and displayed addressee-constructions, the narratee position is less than a proper part of the framework of the telling and is rather an integral device in narrational strategy. Almost invariably, the narratee is addressed by an intradiegetic narrator, i.e., not the narrator of the narrative in our foundational sense (the source or agent for everything that gets told) or, in Bal's words (1985: 120): "that agent which utters the linguistic signs that constitute the text."

The 'implied reader' is another reader-based construct, like the implied author: it is a picture, based on the text in its totality, of the kind of reader or archetypal reader that real readers assume that the text has or had in mind as its audience. Inferencing and stereotyping is involved in positing any text's implied reader. It usually seems easier to sketch the implied reader for narratives that are themselves rather generic and formulaic; it is harder to say who is, or is not, the implied reader of any particular literary masterpieces. The notion of the implied reader, and its implication that certain readers are directly addressed or interpellated whereas others are not, is always likely to provoke contention and controversy. But the ascription of a particular kind of implied reader to particular kinds of texts certainly happens, and to that extent this secondary role or notion is valuable. Rightly or wrongly, in the face of a certain kind of writing (which appears to treat one gender or ethnic group or nationality or class or professional or technical group, etc., as insiders) we assume that the author had a particular kind of reader in mind. Nevertheless, actual readers and audiences can assimilate stories in quite unpredicted ways, seeing a different point to them and picturing quite dissimilar authors of them.

Relations between Story and Narration

Among the more significant of these is the time relation between postulated events and their narration. The commonsense norm for written narratives, perhaps reflected in the use of past tense, is for events to precede their narration: by anything from just a few minutes to many years. But we can also get 'anterior narration,' a telling of what, it is asserted, will happen. A third type of narration, simultaneous with the action, reports events as if they were currently taking place (in the present tense). Of course, the simultaneity is notional rather than real, creating the effect of minimal story-to-narration distance: such narration is akin to news film, in which we see things as if they were just happening, even if the film is broadcast many hours after the incidents have taken place. Intriguing subsidiary effects also seem to derive from use of simple present tense in literary narration, reflective of that tense's commonest uses: particularly, a sense of habituality and even of the quasigeneric in some of the events and states reported. Simultaneous present-tense narration is popular with many contemporary novelists (Updike, Bradbury, Coetzee, Gordimer, and many more).

Framing or embedding relations are also important – for example, the coordinate chaining of several stories within a single text or the embedding of one story (told by a character, for example) within another (about that character). In Genette's terms, the latter case is one of a main story (the diegetic level) narrated by an extradiegetic narrator and an embedded story (the hypodiegetic level) with an intradiegetic narrator. Hypodiegetic narratives commonly serve to advance the action of the first narrative, to explain the background of the first narrative (analepsis is often involved here), or, through similarity of theme with that of the first narrative, to enhance that theme by implicit comparison.

A Typology of Narrators

Literary criticism uses a number of well-established terms for distinguishing kinds of narrator and, by extension, kinds of narration, and many of them continue to be used by linguists. The terms often appear to constitute binary alternatives: *third-person* vs. *first-person* narration; within third-person narration, *omniscient* vs. *limited* narration; and, within omniscient narration, *intrusive* vs. *impersonal* narration. Although invaluable, these terms are far from uncontroversial, and they also direct attention to the narrator, whereas the schemes to be introduced next focus more directly on the narration (and derive tentative characterizations of narrators therefrom). These latter schemes are thus more text linguistic and less psychological in orientation, and thus more suited to a linguistic study of narrative.

Following Genette, first distinctions are made between narratives where the narrator figures within the world of the story they tell (intradiegetic), or is outside it (extradiegetic); and where she or he is an involved story participant (homodiegetic) or a peripheral reporter (heterodiegetic). More linguistically complex are gradations in the narrator's prominence within the telling. The kinds of textual material listed following are indicative – in order of increasing intrusiveness – of narratorial presence and of claims of increasingly full knowledge and understanding of whatever story is articulated:

a. Descriptions of settings
b. Identification of characters
c. Temporal summaries
d. Definition of characters

e. Reports of what characters did not think or say
f. Commentary: interpretation, judgment, and generalization

There are also degrees of intrusion and understanding within any of these stages; for example, descriptions of the same setting may range from the vague and superficial to the precise and detailed. Such a scheme is one way of attempting to measure narratorial control or power or more precisely the effects and illusion of control (or 'mastery' and management) that a particular style of narration conveys to the reader. But it is not just a matter of control – as in a sense the reader knows that the author controls everything anyway. It is perhaps more the effect of the narrator displaying their foreknowledge of what (they know) will transpire, the final nature of the characters, etc.; some narratives do not advertise or display their possession of this foreknowledge.

An alternative and equally effective typology of narrators is of the kind suggested by Uspensky (1973), whose approach is congruent in many respects with the early 20th-century Jamesian poetics of Lubbock. Fowler (l986) is a convenient exposition of this typology, in which there are just four basic types of narration, grouped into pairs on the basis of whether the narration is internal and intrusive or rather external and limited:

> Internal narration is, then, narration from a point of view within a character's consciousness, manifesting his or her feelings about and evaluation of the events and characters of the story (which I shall call type A); or from the point of view of someone who is not a participating character but who has knowledge of the feelings of the characters – the called 'omniscient' author (type B). 'External' point of view relates the events, and describes the characters, from a position outside of any of the protagonists' consciousnesses, with no privileged access to their private feelings and opinions (type C), and in some cases actually stressing the limitations of authorial knowledge, the inaccessibility of the characters' ideologies (type D) (Fowler, 1986: 135).

In recent years, as an interesting revision of the Fowler/Uspensky scheme, which yields nine distinct narrative modes, Simpson (1993) has proposed a typology that merges two three-way distinctions. The first of these is between first-person, third-person narratorial and third-person reflector (or 'limited' to one character, as in Jamesian novels) types of narration; as these are familiar distinctions no more need be said about them here. The second three-way distinction is between narration that is positive and 'engaged' in modality (especially that expressing wishes, desires, and obligations) and in evaluation (including epithets and generic sentences); narration that is negative and 'dissociated' in modality (especially that expressing epistemic uncertainty, and assertions qualified by perceptual language: what *seemed*, *appeared* to be the case, etc.) and in evaluation; and narration, which is neither of these, but neutral, 'objective,' largely confined to the observable facts. This last, neutral mode is suited to physical description rather than psychological development (as in Camus and Hemingway). Each of the voices (first-person, third-person narratorial, etc.) can adopt any of the three stances (positive, negative, neutral), giving rise to nine notional distinct modes of narration. In practice, actual narratives can modulate frequently and subtly between these modes, especially among the three posited stances (and of course the more numerous the postulated types, the more noticeable such modulation becomes).

In Simpson's scheme as in Fowler's, a major emphasis is on identifying the linguistic markers of these distinct narratorial stances toward the material that is being reported. But in both these schemes it could also be suggested that so much bearing on 'point of view' is addressed that the phenomenon known as focalization, to be described in the following section, really has no scope for fully independent existence.

Focalization

In the process of telling a narrative, and the concomitant specifications of time and place, some perspective or other is always implied as the vantage point from which spatiotemporally determinate events are related. This inescapable adoption of a (limited) perspective in narrative, a viewpoint from which things are seen, felt, understood, and assessed is now (following Genette, and Bal) widely referred to as 'focalization.' Focalization is least problematically a matter of visual perception (cf. the Anglo-American counterpart critical term: point of view). But in a more liberal interpretation it concerns all aspects of narrative orientation, including the cognitive, emotive, and ideological.

Unlike the older notion of point of view, the term focalization may help to keep analytically distinct two major aspects of narrative practice:

a. The orientation from which what gets told is told
b. The individual who seems to be the source for whatever words are used in the telling

These two aspects may be summarized in the question, 'From whose perspective do we "perceive"?' and 'Whose words do we "hear"?' In many narratives, perspective and speaking are sourced in a single individual. But speaking/thinking and seeing need not come from the same agent. There are numerous

cases where a narrator 'undertake[s] to tell what another person sees or has seen' (Rimmon-Kenan, 2002: 72). In the early chapters of *Great Expectations*, for example, the narrator is Pip the adult, with an adult's extended vocabulary, whereas the focalizer is Pip the child. A corollary of the notion of focalizer or agent-of-the-focalization is that there must also be someone or something that is the object of the process: this entity is termed the 'focalized.'

Focalization may be external or internal. External focalization occurs where the focalization is from an orientation outside the story and is not associatable with that of any character within the text: in such cases the narrator/focalizer distinction tends to collapse. Internal focalization usually takes place inside the setting of the events and almost always involves a character–focalizer, though some unpersonified stance could be adopted. In Faulkner's 'Barn Burning,' the boy Sartoris is often the focalizer, because the story is told largely from his orientation, though he is not directly responsible for the words used, as this extract from the opening indicates:

> The Store in which the Justice of the Peace's Court was sitting smelled of cheese (1). The boy, crouched on his nail keg at the back of the crowded room, knew he smelled cheese, and more: from where he sat he could see the ranked shelves close-packed with the solid, squat, dynamic shapes of tin cans whose labels his stomach read, not from the lettering which meant nothing to his mind but from the scarlet devils and the silver curve of fish . . . (2). He could not see the table where the Justice sat and before which his father and his father's enemy stood, but he could hear them (3).

Here, sentence (2) expresses exclusively the boy's orientation, whereas (1) is less specific, what anyone inside the store would perceive; and (3) mixes the boy's focalization ('he could hear') with information about the relative positions of the Justice and his father and the table, which we are explicitly told the boy could not see.

Like the two types of focalizers, there are also two types of focalized, where the distinction is between viewing from outside or from within.

The great interest in focalization lies in its function of revealing both the focalized and the focalizer. Here, too, one can distinguish between focalizeds that readers accept exist in the world of the narrative and those taken to be dreams, fantasies, or other figments of the character–focalizer's imagination. Some narratives productively exploit the reader's uncertainty as to whether what is focalized is actual – and potentially public experience – or imagined and hence an index of psychosis (a celebrated example is James's *The Turn of the Screw*).

A final facet of focalization–variation is the ideological. It could be said that all text containing either explicit or implicit evaluation of the major categories or classifications that inform our daily lives and/or evaluation of known individuals or groups or positions that are regarded as ideological is disclosing significant ideological orientations or focalizations. Often, it seems, one ideology or worldview, of an external narrator–focalizer, is the dominating norm, and any characters' ideologies that deviate from this standard are at least implicitly (and sometimes explicitly) censored. On the other hand, there may be a juxtaposition of different ideological orientations without any overt adjudication between them, so that the reader is torn between different views of certain events in particular and (by extension) the world in general (on this rich topic, see Bakhtin, 1981; *see also* **Dialogism, Bakhtinian**).

Unreliable Narration

A narrator may willfully or unwittingly distort, mislead, or suppress important information. The interest is primarily in the reliability or otherwise of intradiegetic narrators, i.e., narrators visible – if only by way of the first-person pronoun – within the narrative. Unreliability constitutes another text-processing burden for the reader; and the linguistic interest is in specifying the chief text–linguistic patterns or indices of unreliability and of levels of unreliability. But it remains true that narratorial unreliability is not always traceable to textual cues – particularly where the unreliability is in essence a simple silence or secrecy on certain issues.

Unreliability takes many forms, though the general principle is that unreliability is attributable to any narrator the veracity of whose account the reader comes to suspect. Some narrators are liars or consciously flatter themselves and are clearly intended to be seen as attempting to deceive. Other narrators mislead for less culpable reasons: e.g., the limited knowledge of a young narrator, or one with limited mental capacity like Benjy in *The Sound and the Fury*. Personal involvement with events – especially when the narrator is a direct or indirect victim of those events – may often give rise to narratorial suppression, distortion, prevarication, and so on (as one example, consider Rosa's account of events in *Absalom! Absalom!*). Abnormal values may give rise to a type of unreliability that makes it difficult to decide whether we have a normal narrator telling terrible things with much covert irony, or simply an awful narrator. The great attraction and danger of unreliable narration is, as Booth (1961) rather regrets, that no clear moral or ideological stance is spelt out and held

to, and we as readers are not *told* what to think. But a fully articulated theory of what unreliability consists in, and of the grounds for attributing it to one narrator but not another, remains elusive and contentious. For important recent discussions of the topic, which also usefully challenge us to rethink what we mean by *reliable* narration, see Yacobi (1981), Wall (1994), Nünning (1999), and Fludernik (1999).

Psycholinguistic and Cognitive Studies of Narrative

Much psycholinguistic research has been undertaken into the question of whether humans develop mental frameworks specifying the standardly accepted linear and hierarchical structuring of stories, which frameworks they can then use as an aid in the comprehension, storage, and recall of actual stories (see especially Mandler, 1984). These mental frameworks are termed story schemata, and their probable configuration can be represented on the page as a grammar. Hence researchers in this area are often described as story grammarians.

New applications of story grammar theory continue to be proposed. The primary foci of attention remain story recall and comprehension in normal and cognitively impaired adults and children – for example, presenting one group of readers with a story that is slightly scrambled story-grammatically, and noting the effect on readers' rate and extent of recall when compared with a control group's performance with an unscrambled ('grammatical') version of the story. But besides studies of recall and comprehension, the theory has also been interestingly invoked in identifications of and predictions about defective ('ungrammatical') stories.
